Received 18 January 2015; Accepted 18 January 2015

Cardiovascular diseases (CVD) are the leading cause of death, also in diabetic women. Since 1998, when Haffner et al. [1] stated that subjects with type 2 diabetes mellitus (T2DM) had a CVD risk "equivalent" to previous myocardial infarction, a large number of studies have shown that this relative risk for CVD due to diabetes is greater in women than in men [2].

CVD in diabetic subjects is not entirely related to chronic hyperglycaemia and a number of other factors such as dyslipidemia, hypertension, hormonal, genetic, and environmental factors, as well as low-grade systemic inflammation and endothelial damage, lifestyle behaviours, adherence to therapies, and/or psychosocial factors may contribute to the worst outcomes observed in diabetic women. Notably, it is increasingly recognized that many of these factors show gender differences in their prevalence and/or association with CVD events, and this aspect should be specifically targeted when aiming at primary or secondary CVD prevention in diabetic subjects.

In this special issue, we looked at CVD in women with diabetes from different perspectives, giving a great contribution to this topic, in terms of mortality, management of risk factors, and therapies.

Two papers of this special issue looked at sex differences in CVD mortality associated with diabetes. One conducted on a large population-based sample from Italy demonstrated an excess of mortality in diabetic subjects as compared to nondiabetic ones and a greater impact of diabetes in females than in males for mortality for all causes, for CVD, and f
myocardial infarction and renal causes. In the other stu
G. Luo et al. showed in a retrospective analysis that fasti
plasma glucose was an independent predictor of in-hospi
mortality for nondiabetic female patients.

Gender-specific prevalence and management of maj
and emerging CVD risk factors in different populations we
also the main topic of several papers of this special issue.

The paper by S. Chen et al., with a very interesting expe
imental protocol, clarified the relationships of albuminur
a well-recognized CVD risk factor, with circulating lev
of angiopoietin-1 (Ang-1), Ang-2, and vascular endothel
growth factor (VEGF) in serum and urine.

Potential gender differences in the distribution and co
trol of major CVD risk factors were investigated in anoth
three very large high-risk populations. Thus, in the eCont
Study, a study on 286,791 patients with T2DM in Catalon
Spain, J. Franch-Nadal et al. found that cardiometabo
control was worse in subjects with prior CVD; but cont
of several risk factors showed gender differences, favouri
women with prior CVD only for smoking and BP, where
LDL-cholesterol (LDL-C) levels were remarkably unco
trolled in women both with and without CVD.

The results of an overall bad control of LDL-C in wom
were also demonstrated in a very large Italian diabe
outpatient population from the Annals Study Initiative. T
study, conducted on 415.294 patients (45.3% women) fro

Estrogen Signaling and Cardiovascular Disease

Elizabeth Murphy
Cardiac Physiology Section, Systems Biology Center, NHLBI, NIH Bethesda, MD

I. How Does Estrogen Alter Cell Function?

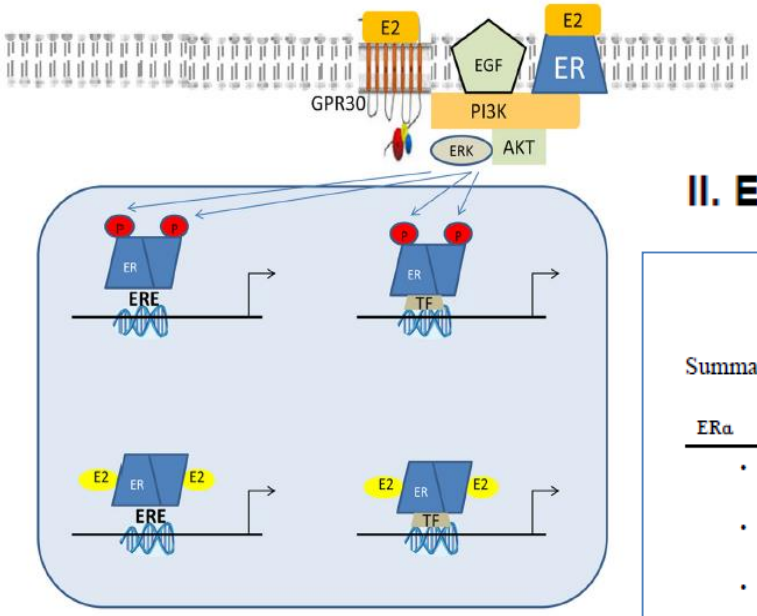

Figure 1.
Figure 1 shows the major mechanism by which ER can alter gene expression. Estrogen (E2) binds to ER resulting in dimerization and recruitment of co-regulators (not shown due to space limitations). The estrogen-ER complex binds to estrogen response elements (ERE) on the DNA resulting in altered gene transcriptions. Estrogen can also alter gene transcription by binding to transcription factors (TF) such as AP1. In addition, ER can be phosphorylated by growth factors and other plasma membrane estrogen receptors that are coupled to kinase signaling. Phosphorylated ER can activate gene transcription in a ligand-independent manner.

II. ERα and ERβ differentially regulate gene expression

Table 1

Summary of known genomic function associated with ERα and ERβ

ERα	ERβ
• Increases left ventricular mass and volume[159];	• Reduces pathologic cardiac hypertrophy[4];
• Reductions of infarct size after myocardial infarction[159];	• Prevents increases mortality in chronic heart failure[165, 166];
• Cardioprotection against ischemia-reperfusion injury[160–162];	• Cardioprotection against ischemia-reperfusion injury[41];
• Regulates GLUT4 expression[163];	• Regulation of vascular function and blood pressure[133];
• Regulates cardiac growth[164].	• modulates sex-specific response of the heart to exercise[50];
	• Decreases inflammatory response[41].

The Expanding Complexity of Estrogen Receptor Signaling in the Cardiovascular System

Sara Menazza and **Elizabeth Murphy**
Systems Biology Center, National Heart Lung and Blood Institute, National Institutes of Health, Bethesda, MD 20892

Gli estrogeni svolgono moltelici effetti benefici sull'apparato cardiovascolare

Menazza and Murphy

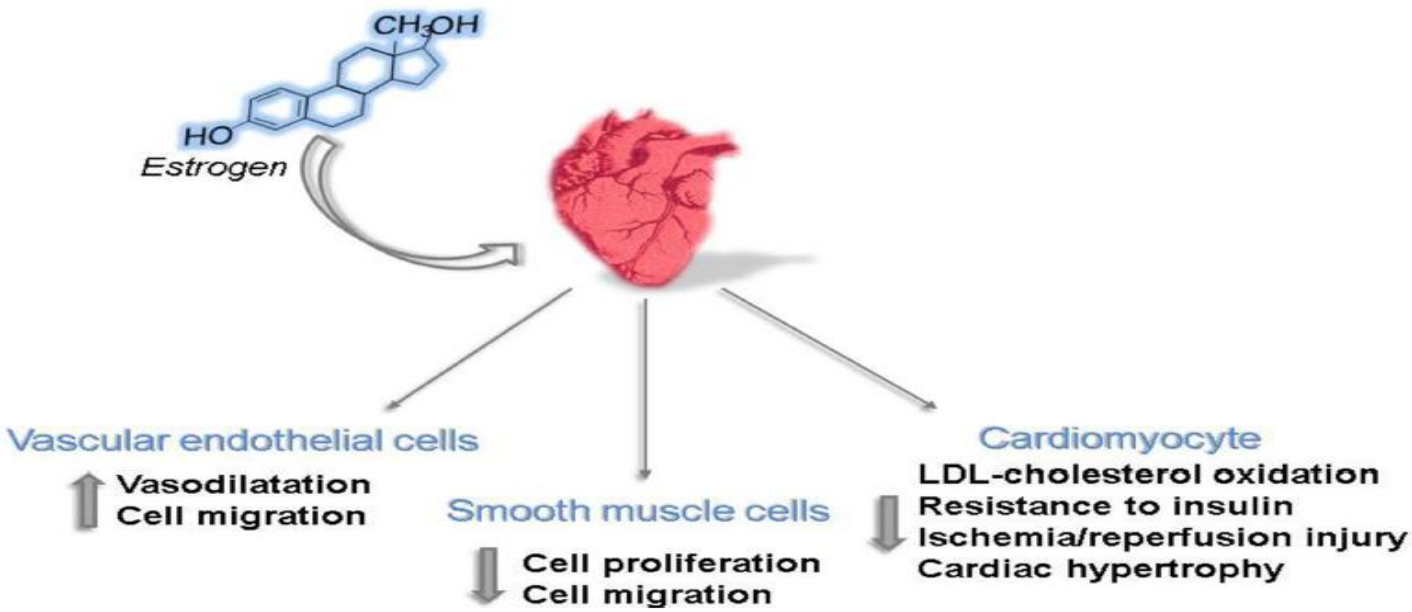

Figure 1. Effects of estrogen on the heart
Estrogen has many pleiotropic effects on the cardiovascular system. Estrogen can impact cardiovascular health and disease by direct effects: (i) on the vascular endothelial cells promoting vasorelaxation, cell proliferation and migration; (ii) on vascular smooth muscle cells decreasing cell proliferation and migration and (iii) on cardiomyocytes reducing LDL-cholesterol level and protecting against insulin resistance, infarct size and ischemia–reperfusion injury and cardiac hypertrophy.

Diabetes is a potent Cardiovascular (CVD) Risk Factor in men and women

Diabetes as a risk factor for stroke in women compared with men: a systematic review and meta-analysis of 64 cohorts, including 775 385 individuals and 12 539 strokes

Sanne A E Peters, Rachel R Huxley, Mark Woodward

Summary

Background Diabetes mellitus is a major cause of death and disability worldwide and is a strong risk factor for stroke. Whether and to what extent the excess risk of stroke conferred by diabetes differs between the sexes is unknown. We did a systematic review and meta-analysis to estimate the relative effect of diabetes on stroke risk in women compared with men.

Gender-based differences in glycaemic control and hypoglycaemia prevalence in patients with type 2 diabetes: results from patient-level pooled data of six randomized controlled trials

ORIGINAL ARTICLE

A. Kautzky-Willer[1], L. Kosi[1], J. Lin[2] & R. Mihaljevic[3]

[1] *Division of Endocrinology and Metabolism, Gender Medicine Unit, Medical University of Vienna, Vienna, Austria*
[2] *Novosys Health, Flemington, NJ, USA*
[3] *Scientific Affairs, Diabetes, Sanofi, Vienna, Austria*

Aims: To determine the impact of gender on glycaemic control and hypoglycaemia in insulin-naïve patients with type 2 diabetes (T2DM).

Methods: Data were pooled from six randomized clinical trials of insulin glargine or NPH insulin in insulin-naïve, inadequately controlled patients. Female [n = 1251; mean glycated haemoglobin (HbA1c) level 8.99%, age 56.91 years, diabetes duration 9.84 years] and male patients (n = 1349; mean HbA1c 8.9%, age 57.47 years, diabetes duration 10.13 years) were started on and treated with insulin glargine or NPH insulin for 24–36 weeks. HbA1c and fasting blood glucose levels, percent achieving HbA1c target of <7% and insulin dose change were recorded.

Results: For both men and women, HbA1c levels were significantly reduced over time ($p < 0.001$); a significantly greater HbA1c reduction was observed in men than in women (−1.36 vs. −1.22; $p = 0.002$). Significantly fewer women achieved target HbA1c of <7% ($p < 0.001$). At the study end, women had a significantly higher insulin dose/kg than men (0.47 vs. 0.42 U/kg; $p < 0.001$). The incidence rates of severe and severe nocturnal hypoglycaemia were significantly higher in women (3.28% vs. 1.85%; $p < 0.05$ and 2.24% vs. 0.59%; $p < 0.001$, respectively). Women were more likely to experience severe hypoglycaemia [odds ratio (OR) 1.80; 95% confidence interval (CI) 1.08, 3.00; $p = 0.02$] and severe nocturnal hypoglycaemia (OR: 3.80; 95% CI 1.72, 8.42; $p = 0.001$).

Conclusions: These observations confirm studies that found a smaller improvement in HbA1c and greater hypoglycaemia in women during insulin treatment. Physicians should be aware of the need to determine and closely monitor dosing, particularly in women, to optimize the balance between glycaemic control and hypoglycaemia risk.

Keywords: gender, hypoglycaemia, insulin glargine, NPH insulin, type 2 diabetes

Insulin dose is higher in T2DM women than men

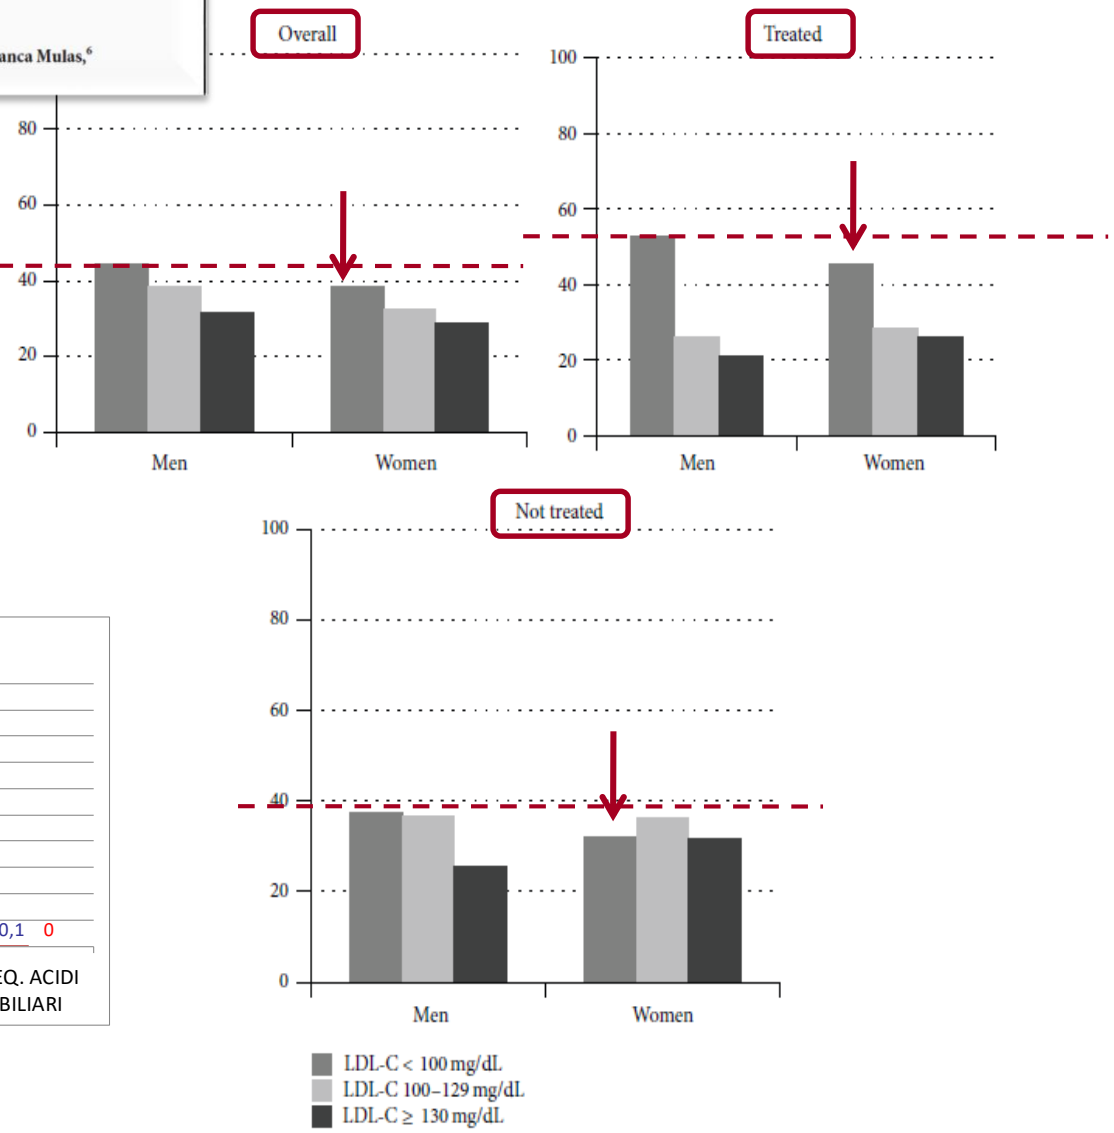
Age- and Gender-Related Differences in LDL-Cholesterol Management in Outpatients with Type 2 Diabetes Mellitus

Giuseppina Russo,[1] Basilio Pintaudi,[2] Carlo Giorda,[3] Giuseppe Lucisano,[2] Antonio Nicolucci,[2] Maria Rosaria Cristofaro,[4] Concetta Suraci,[5] Maria Franca Mulas,[6] Angela Napoli,[7] Maria Chiara Rossi,[2] and Valeria Manicardi[8]

International Journal of Endocrinology

La percentuale di pazienti con DM2 che raggiungono i *target* di LDL-C è sempre più bassa nelle donne, sia trattate che non trattate



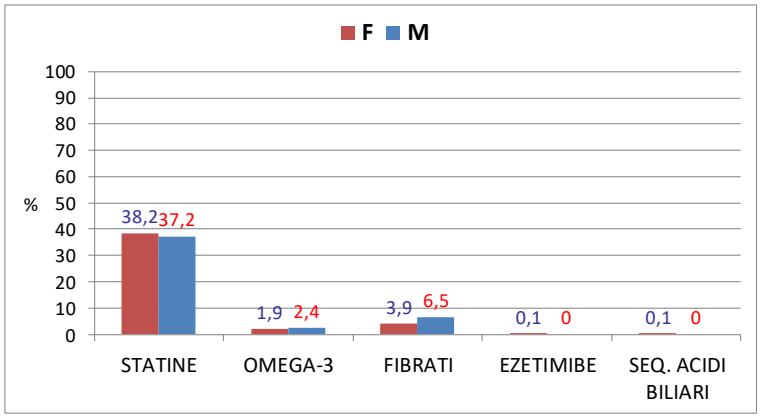


FIGURE 1: LDL-C classes according to gender and lipid-lowering treatment.

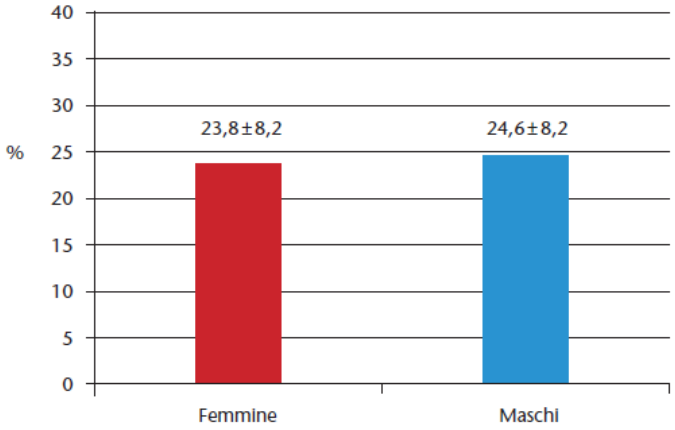
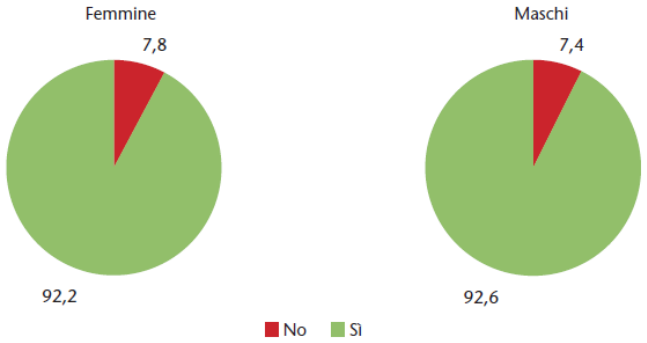
In Italy, quality of care is comparable in T2DM men and women

Score Q medio per sesso



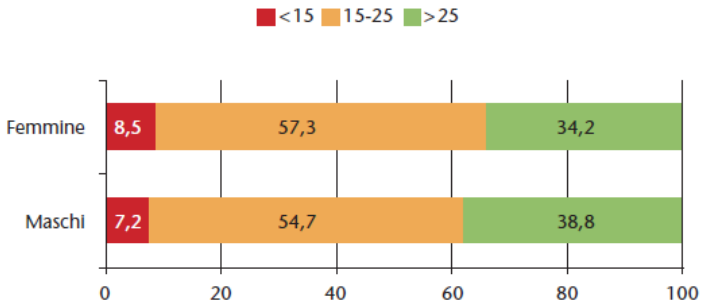
Il punteggio medio dello score di qualità complessiva (score Q) risulta leggermente più basso nelle donne.

Percentuale di soggetti ai quali è stata eseguita almeno una misurazione dell'HbA1c



I dati non mostrano una sostanziale differenza nella percentuale di soggetti che hanno ricevuto almeno una volta il monitoraggio dell'HbA1c negli ultimi 12 mesi; le percentuali sono estremamente elevate, superiori al 90%, in entrambi i sessi.

Score Q in classi per sesso



Uno score Q inferiore a 15 è stato rilevato solo in una bassa percentuale di casi, ma in una quota leggermente più elevata di donne. Analogamente, un punteggio superiore a 25 è presente in oltre un terzo dei casi, sebbene questa percentuale sia lievemente più bassa nelle donne.

Gene-Gender interactions on CVD risk factors

GENDER MEDICINE/VOL. 4, SUPPL. B, 2007

Gender, a Significant Factor in the Cross Talk Between Genes, Environment, and Health

Jose M. Ordovas, PhD

Nutrition and Genomics Laboratory, JM-USDA-Human Nutrition Research Center on Aging at Tufts University, Boston, Massachusetts

Results: Evidence from some key factors in lipid metabolism (apolipoprotein E [*APOE*]) and obesity (perilipin [*PLIN*]) indicates that the interplay between genes, gender, and environmental factors modulates disease susceptibility. In the Framingham Heart Study, complex interactions have been shown between a promoter polymorphism at the apolipoprotein A1 gene, gender, and dietary polyunsaturated fatty acid intake that modulate plasma concentrations of high-density lipoprotein cholesterol. Likewise, highly and clinically relevant interactions have been observed between the *APOE* gene common alleles *APOE2*, *APOE3*, and *APOE4*, gender, and smoking that determine cardiovascular disease risk. Most interesting is the gender-dependent association between common polymorphisms at the *PLIN* locus and obesity risk that has been replicated in several populations around the world.

APOC3

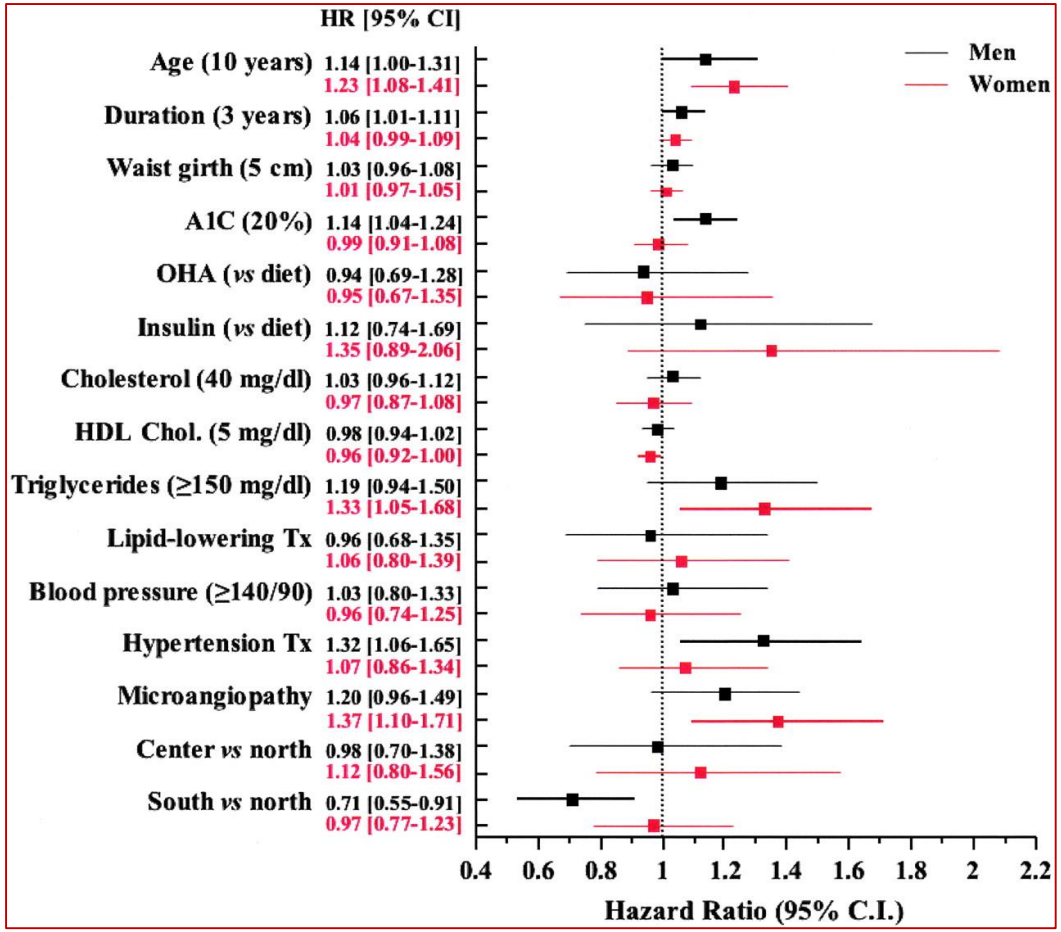
FOR THE DIABETES AND INFORMATICS STUDY GROUP, ASSOCIATION OF CLINICAL DIABETOLOGISTS, ISTITUTO SUPERIORE DI SANITÀ

Diabetes is estimated to be responsible for 5.2% of all deaths (1). Since the Framingham Study (2), epidemiology has consistently shown that diabetes confers an increased risk for coronary heart disease (CHD) and cardiac mortality (3–6). Salient features of this association are the following: *1*) relative



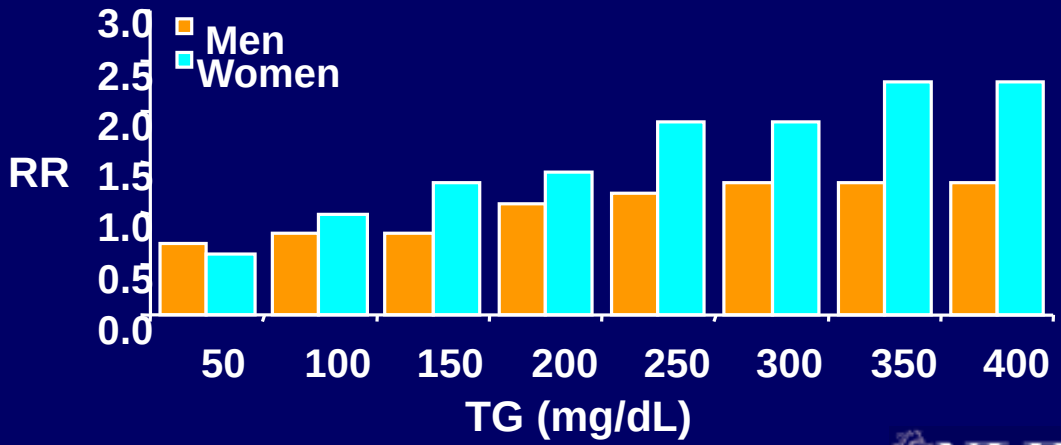
Independent predictors of incident CHD in diabetic men (black) and women (red).

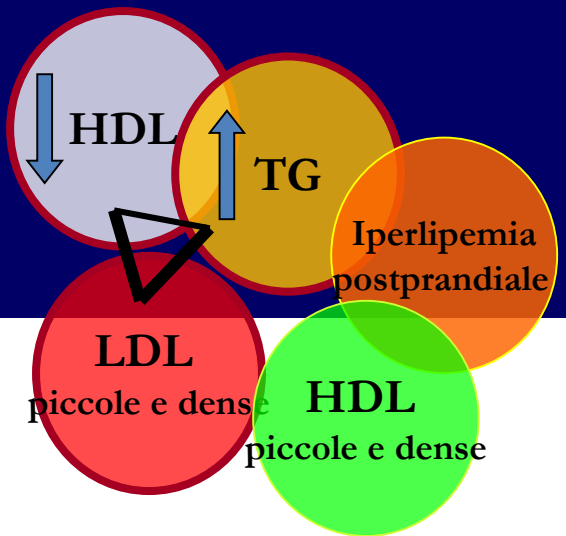
American Diabetes Association.

Diabetes Care 30:1241–1247, 2007

Impact of TG Levels on Relative Risk of CHD:
Framingham Heart Study

La dislipidemia aterogena è un importante fattore di rischio nelle donne





Castelli, Can J Cardiol 1988

HDL

Bassi livelli di colesterolo HDL aumentano il rischio cardiovascolare

HDL
piccole e dense

HDL-C as a predictor of CHD risk.
(A) Data from a 6-year follow up of the PROCAM study showing that the incidence of CHD decreases with higher levels of HDL-C (Assmann et al., 1996).

(B) Data from the Framingham study showing that high levels of HDL-C reduce the risk of CHD at all levels of LDL-C (Gordon et al., 1977).

HDL cholesterol ≥60 mg/dL counts as a "negative" risk factor; its presence removes one risk factor from the total count.

Table 2. Plasma lipids, lipoprotein and apo-A-I-containing HDL subpopulations in CHD-free pre- and postmenopausal women with and without type 2 diabetes.

	Type 2 Diabetic women		Control women			
	Pre-menopause	Post-menopause	Pre-menopause	Post-menopause	P1	P2
T-C (mg/dl)	189.0 ± 32.4	192.5 ± 26.9 ↑	179.8 ± 29.3	203.9 ± 24.7 ↑	NS	0.04
HDL-C (mg/dl)	45.9 ± 13.8	48.6 ± 13.4 ↑	56.9±11.8	55.6±11.7 ↑	0.0004	0.01
LDL-C (mg/dl)	127.1 ± 30.3 ↑	122.3 ± 24.6	116.3±27.4	134.2 ± 27.3 ↑	NS	0.04
VLDL-C (mg/dl)	28.0 ± 20.3 ↑	20.8 ± 9.1	15.6 ± 5.3	19.4 ± 8.7 ↑	<0.001	<0.001
Triglycerides (mg/dl)	140.1 ± 101.5 ↑	104.1 ± 45.5	78.2 ± 26.5	96.8 ± 43.7 ↑	<0.001	<0.001
Apo-A-I- containing HDL subpopulations						
α-1 HDL (mg/dl)	18.2 ± 8.2	20.2 ± 9.6	22.8 ± 8.1	23.8 ± 10.8	0.02	0.01
α-2 HDL (mg/dl)	42.5 ± 11.0	40.3 ± 8.2	45.9 ± 8.6	45.1 ± 9.4	NS	0.01
α-3 HDL (mg/dl)	17.8 ± 6.7	18.5 ± 4.3	16.4 ± 3.6	16.3 ± 3.9	NS	NS
Preα-1 HDL (mg/dl)	5.7 ± 3.4	5.3 ± 3.4	6.9 ± 2.5	6.6 ± 4.1	NS	NS

Modified from Russo GT et al.[48]. Values are n, mean ± SD. T-C, total cholesterol; -C, total cholesterol; LDL-C, low- density lipoprotein cholesterol; HDL-C, high-density lipoprotein cholesterol; VLDL, very low-density lipoprotein; NS, not significant. P1, pre-menopause diabetic vs controls; P2, post-menopause diabetic vs controls.

Gender differences in chronic kidney disease

Kunitoshi Iseki[1]

Women live longer than men. Can this phenomenon be explained by chronic kidney disease (CKD)? Gender differences in the prevalence and incidence of CKD are discussed.

Kidney International (2008) **74**, 415–417. doi:10.1038/ki.2008.261

Predictors of chronic kidney disease in type 2 diabetes

A longitudinal study from the AMD Annals initiative

Salvatore De Cosmo (MD)[a,*], Francesca Viazzi (MD)[b], Antonio Pacilli (MD)[a], Carlo Giorda (MD)[c], Antonio Ceriello (MD)[d], Sandro Gentile (MD)[e], Giuseppina Russo (MD)[f], Maria C. Rossi (MD)[g], Antonio Nicolucci (MD)[h], Pietro Guida (MSC)[h], Roberto Pontremoli (MD, PhD)[b], and the AMD-Annals Study Group

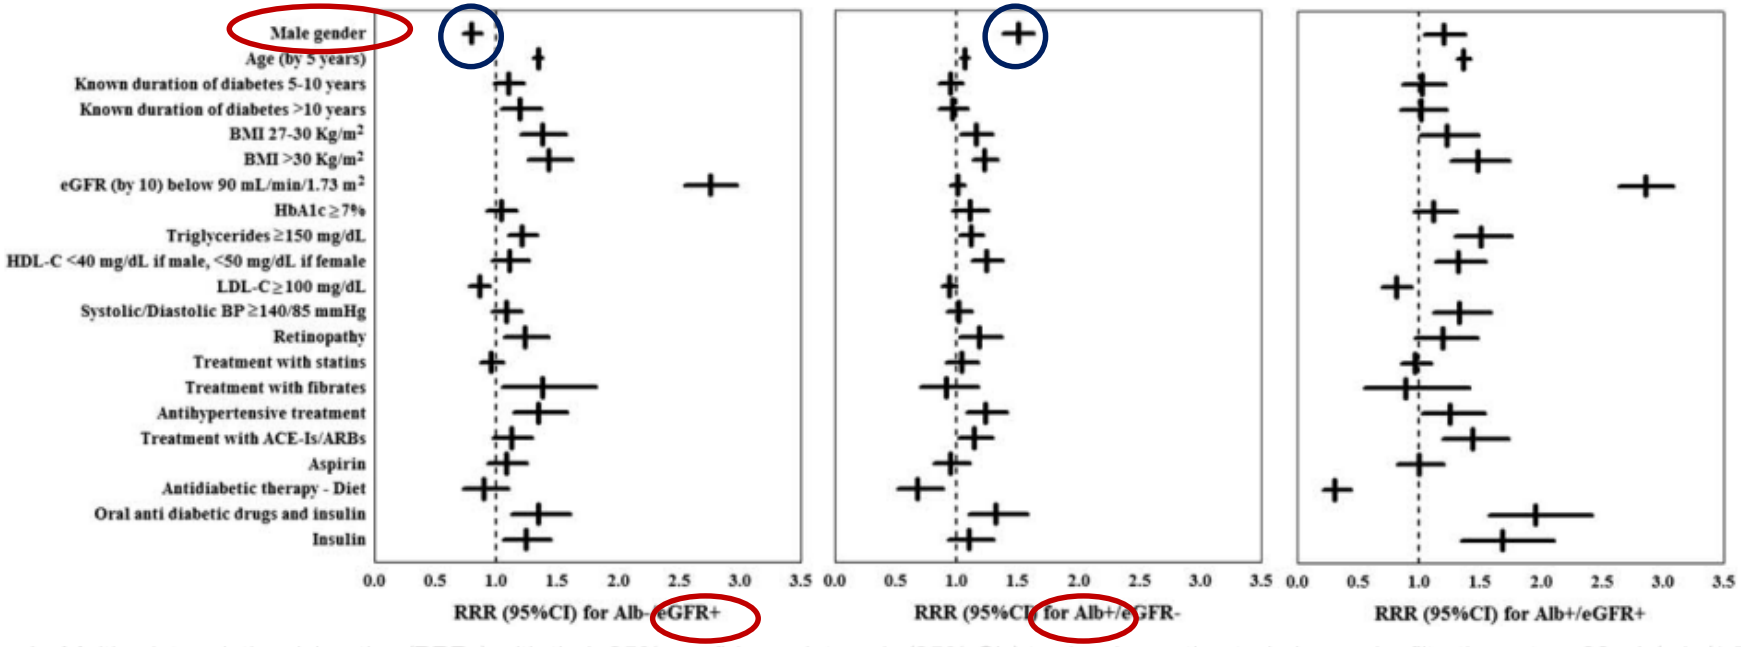

Figure 1. Multivariate relative risk ratios (RRRs) with their 95% confidence intervals (95% CIs) to develop estimated glomerular filtration rate <60 mL/min/1.73 m^2 (Alb−/eGFR+) = albuminuria (Alb+/eGFR−) = or both (Alb+/eGFR+). Antidiabetic therapy was analyzed by using oral antidiabetic drugs as reference category. Analysis performed by using a multinomial logistic regression model with the missing indicator method for each incomplete variable.

Research: Complications

The influence of sex on renal function decline in people with Type 2 diabetes

A. de Hauteclocque[1], S. Ragot[1], Y. Slaoui[2], E. Gand[3], A. Miot[4], P. Sosner[5,6], J.-M. Halimi[7], P. Zaoui[8], V. Rigalleau[9,10], R. Roussel[11,12,13,14], P.-J. Saulnier[1], S. Hadjadj Samy[1,4,15] for the SURDIAGENE Study group

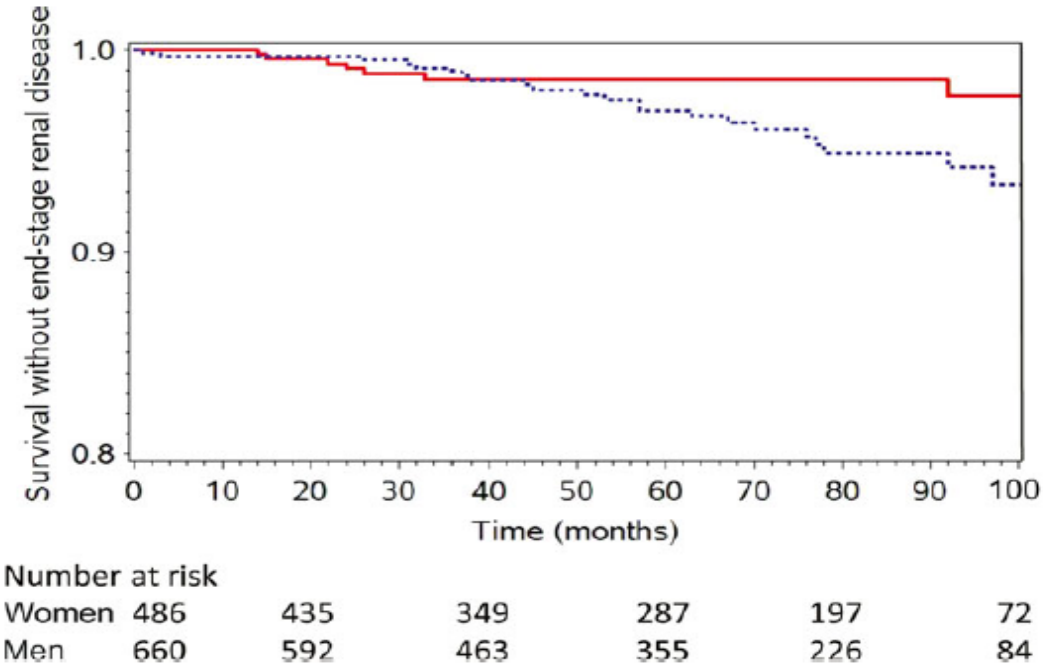

FIGURE 2 Survival without end-stage renal disease according to sex. The thick red line represents survival in women and the dotted blue line survival in men.

Men: OR 1.33 (1.01-1.04)
higher risk of steep decline

What's new?

- Male sex was an independent risk factor of steep eGFR decline.
- Estimated glomerular filtration rate trajectories were significantly different according to sex.
- Survival without end-stage renal disease was higher in women than in men.
- Male sex is suggested as an important independent factor associated with renal function decline in Type 2 diabetes.

Gender-dependent effect of ACE I/D and AGT M235T polymorphisms on the progression of urinary albumin excretion in Taiwanese with type 2 diabetes.

Tien KJ[1], Hsiao JY, Hsu SC, Liang HT, Lin SR, Chen HC, Hsieh MC.

BACKGROUND:

We investigated the gender differences in the effect of ACE I/D and AGT M235T polymorphisms on the prognosis of diabetic nephropathy (DN).

METHODS:

A total of 525 type 2 diabetics were enrolled to participate in this prospective observational study. ACE and AGT gene polymorphisms were analyzed by polymerase chain reaction. The progression of DN was defined as a shift to a higher stage of DN or a doubling of the baseline serum creatinine level by the end of the study.

RESULTS:

The baseline biophysical parameters show no gender differences in progression and non-progression of DN. The women who were ACE D allele carriers were found to be at an increased risk of DN progression compared to those with II genotypes (p = 0.024, OR 2.176). No such difference was seen in male patients (p = 0.619, OR 0.833). After adjusting for confounding factors (age, SBP, DBP, BMI, HbA1c, total cholesterol, TG, HDL-C, LDL-C, ACEI, and ARB) in our multiple regression analysis, these women were still found to be at increased risk of progressing to more severe DN (p = 0.008, OR 3.082) but not the men (p = 0.183, OR 0.586). Neither the AGT TT genotype nor the T allele were associated with the progression of DN in either sex after adjusting for confounding factors.

CONCLUSION:

Our follow-up study suggests that female diabetic carriers of the ACE D allele might be at an increased risk of DN progression.

Sex differences in the impact of diabetes on mortality in chronic dialysis patients

Juan J. Carrero[1,2,*], Renée de Mutsert[3,*], Jonas Axelsson[1], Olaf M. Dekkers[3,4], Kitty J. Jager[5], Elisabeth W. Boeschoten[6], Raymond T. Krediet[7], Friedo W. Dekker[3] and for the NECOSAD Study Group

Methods. This study was a prospective observational cohort study (NECOSAD) of incident dialysis patients with 5 years of follow-up where we calculated male:female odds ratios (OR) and relative risks of mortality (hazard ratio, HR) for the presence of CVD risk factors at the start of dialysis. We also examined the presence of interaction between sex and CVD risk factors in their association with mortality.

Results. In 1577 patients (61% men, 60±15 years), men presented more CVD co-morbidity [OR: 1.88 (95% CI: 1.51, 2.35)] but less diabetes mellitus (OR: 0.70 [0.55, 0.89]) than women. Both sexes presented equal survival [HR 0.98 (0.83, 1.16)]. Women with diabetes had a higher mortality risk [HR 2.93 (2.27, 3.79)] than their male counterparts [HR 1.99 (1.52, 2.59)], showing an interaction effect between sex and diabetes [relative excess risk due to interaction 1.18 (0.37, 2.00)].

Table 3. All-cause and CVD mortality rates for men and women with and without pre-existing diabetes in 5 years after the start of dialysis

	Women		Men	
Variable	Non-diabetes	Diabetes	Non-diabetes	Diabetes
N	457	162	765	193
Person-years (py)	1223.1	332.7	1926.5	433.3
Deaths from all causes	134	105	259	95
Deaths from CVD[a]	62	50	127	49
Deaths from all causes/1000 py	110	316	134	219
Deaths from CVD/1000 py	51	150	66	113

DM, diabetes mellitus; non-DM, without diabetes mellitus; CVD, cardiovascular diseases.
[a]Fourteen causes of death were missing, six in men and eight in women.

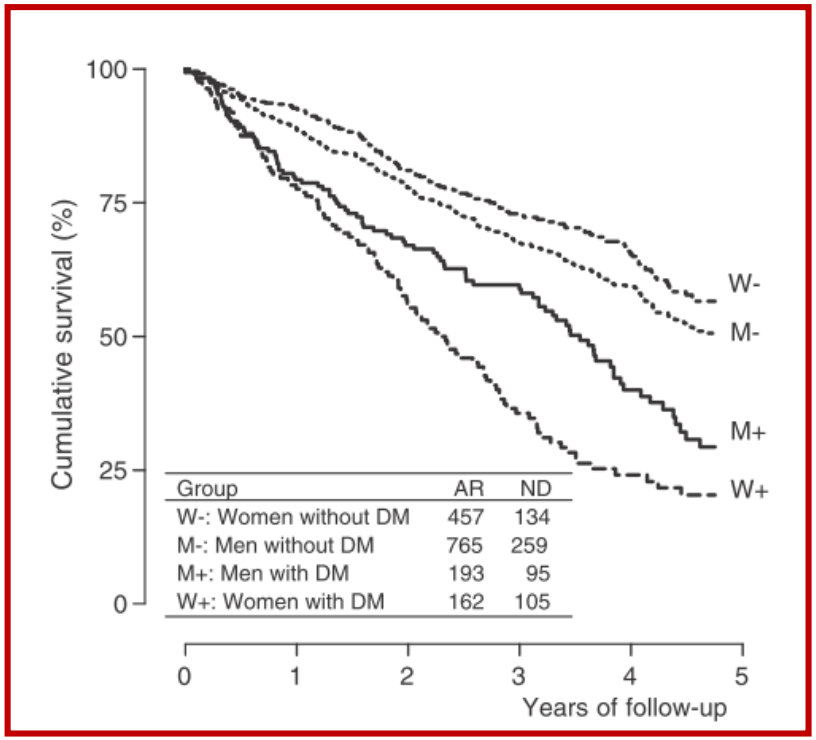

Fig. 1. Cumulative survival of women (W−) and men (M−) without diabetes and men (M+) and women (W+) with diabetes at baseline during 5 years after the start of dialysis (log rank $P < 0.001$); AR, number of patients at risk at the start of dialysis; ND, number of deaths during follow-up.

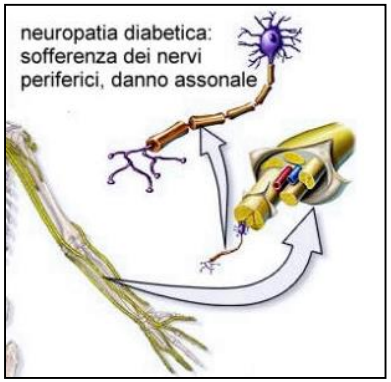
Gender Differences in Diabetic Neuropathy

Diabetic Neuropathy: A Position Statement by the American Diabetes Association

Rodica Pop-Busui,[1] Andrew J.M. Boulton,[2] Eva L. Feldman,[3] Vera Bril,[4] Roy Freeman,[5] Rayaz A. Malik,[6] Jay M. Sosenko,[7] and Dan Ziegler[8]

Diabetes Care 2017;40:136–154 | DOI: 10.2337/dc16-2042



Diabetic neuropathies are the most prevalent chronic complications of diabetes. This heterogeneous group of conditions affects different parts of the nervous system and presents with diverse clinical manifestations. The early recognition and appropriate management of neuropathy in the patient with diabetes is important for a number of reasons:

1. Diabetic neuropathy is a diagnosis of exclusion. Nondiabetic neuropathies may be present in patients with diabetes and may be treatable by specific measures.
2. A number of treatment options exist for symptomatic diabetic neuropathy.
3. Up to 50% of diabetic peripheral neuropathies may be asymptomatic. If not recognized and if preventive foot care is not implemented, patients are at risk for injuries to their insensate feet.
4. Recognition and treatment of autonomic neuropathy may improve symptoms, reduce sequelae, and improve quality of life.

Table 1—Classification for diabetic neuropathies

Diabetic neuropathies
- **A. Diffuse neuropathy**
  - DSPN
    - Primarily small-fiber neuropathy
    - Primarily large-fiber neuropathy
    - Mixed small- and large-fiber neuropathy (most common)
  - Autonomic
    - Cardiovascular
      - Reduced HRV
      - Resting tachycardia
      - Orthostatic hypotension
      - Sudden death (malignant arrhythmia)
    - Gastrointestinal
      - Diabetic gastroparesis (gastropathy)
      - Diabetic enteropathy (diarrhea)
      - Colonic hypomotility (constipation)
    - Urogenital
      - Diabetic cystopathy (neurogenic bladder)
      - Erectile dysfunction
      - Female sexual dysfunction
    - Sudomotor dysfunction
      - Distal hypohydrosis/anhidrosis,
      - Gustatory sweating
    - Hypoglycemia unawareness
    - Abnormal pupillary function
- **B. Mononeuropathy (mononeuritis multiplex) (atypical forms)**
  - Isolated cranial or peripheral nerve (e.g., CN III, ulnar, median, femoral, peroneal)
  - Mononeuritis multiplex (if confluent may resemble polyneuropathy)
- **C. Radiculopathy or polyradiculopathy (atypical forms)**
  - Radiculoplexus neuropathy (a.k.a. lumbosacral polyradiculopathy, proximal motor amyotrophy)
  - Thoracic radiculopathy

Nondiabetic neuropathies common in diabetes
- Pressure palsies
- Chronic inflammatory demyelinating polyneuropathy
- Radiculoplexus neuropathy
- Acute painful small-fiber neuropathies (treatment-induced)

large, community-based survey of 9,710 predominantly type 2 diabetic patients derived from general practice in north-west England, the prevalence of at least neuropathic deficits as defined

Nello studio dei Medici di Medicina generale Inglesi: il *sesso femminile* è associato alla neuropatia

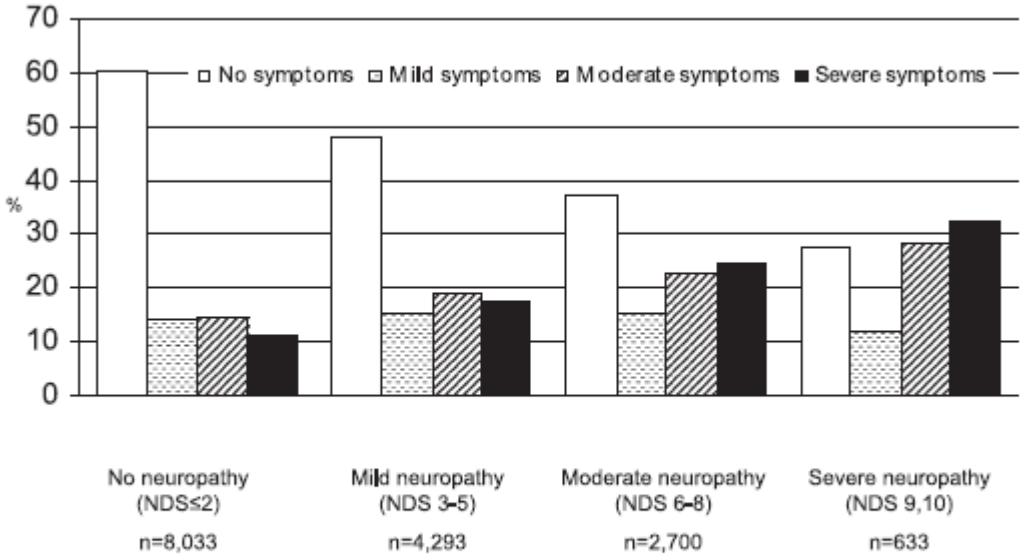

Figure 1—*Percentage prevalence of neuropathic symptoms in 15,659 diabetic patients characterized by their level of clinical neuropathy.*

Effect of sex

A significantly greater proportion of females (38% [2,732/7,212]) than males (31% [2,578/8,423]) reported painful neuropathy symptoms ($P < 0.0001$), despite fewer females than males having clinical neuropathy (NDS ≥6) (19 vs. 23%, $P < 0.0001$). PDN (NSS ≥5 and NDS ≥3) was, similarly, more prevalent in females than males (23 vs. 19%, respectively, $P < 0.0001$). After adjustments for age, diabetes duration, and differences in clinical neuropathy, women still had a 50% increased risk of painful symptoms compared with men (OR = 1.5 [95% CI 1.4–1.6], $P < 0.0001$).

Gender Differences in Diabetes-related Lower Extremity Amputations

Monica E. Peek MD, MPH

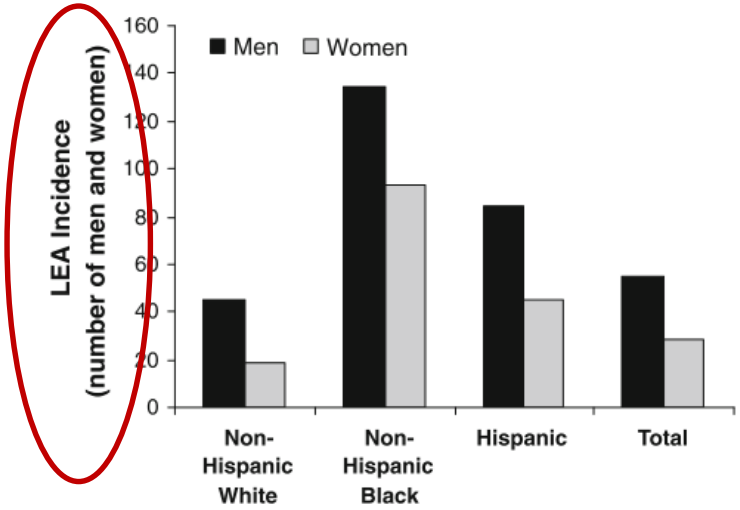

Fig. 1 A graph shows the differences in diabetes-related LEA incidence by race and gender. Men had a higher LEA incidence than women (55 versus 28 LEAs per 100,000 diabetes patients), and the gender differences persisted across racial/ethnic groups: 45 versus 19 LEAs among non-Hispanic white men and women, respectively; 134 versus 93 LEAs among African Americans; and 84 versus 45 LEAs among Hispanic Americans ($p < 0.05$ for all groups).

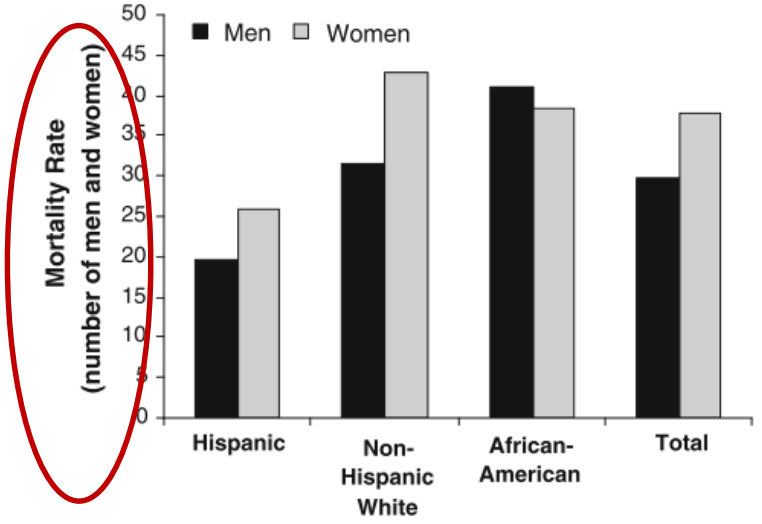

Fig. 2 A graph shows the differences in age-adjusted mortality associated with diabetes-related LEAs by race and gender. Women had a higher mortality rate than men (37.7 versus 29.7 deaths per 1000 amputations), and gender differences were found among whites (43.0 versus 31.5 deaths among women and men, respectively) and Hispanics (25.9 versus 19.7) but not African Americans (38.5 versus 41.5).

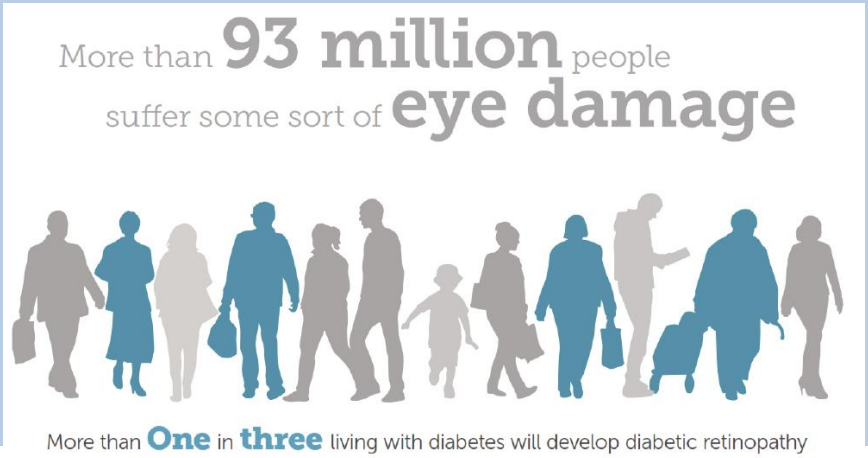
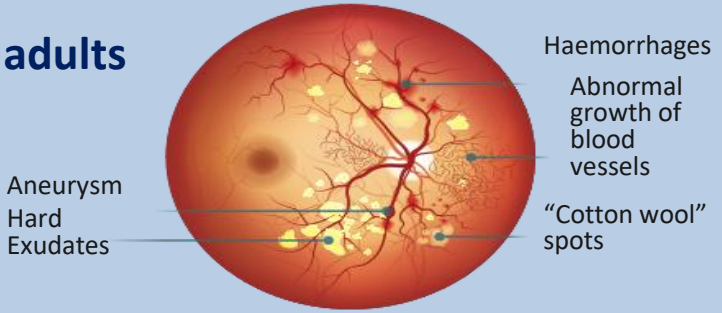
Gender differences in diabetic Retinopathy

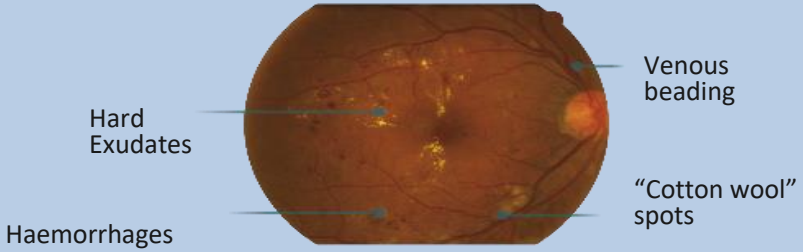
Of the 415 million people worldwide with diabetes in 2015, more than 93 million people currently suffer some sort of eye damage from diabetes

- **33% of subjects with diabetes will develop DR**
- **33% of subjects with DR will have impaired vision**
- **DR is the leading cause of vision loss in working-age adults**



Diabetic retinopathy





Severe non-proliferative diabetic retinopathy with severe diabetic macular edema

SHORT COMMUNICATION

Diabetic retinopathy at diagnosis of type 2 diabetes in the UK: a database analysis

K. Kostev · W. Rathmann

Table 1 Characteristics of patients with type 2 diabetes in general practices in the UK (Disease Analyzer Database) stratified by retinopathy status

Characteristic	All	No diabetic retinopathy	Diabetic retinopathy	OR[a] (95% CI)	
				Univariate	Multivariate
n	12,524	10,139	2,385	–	–
Male sex (%)	56.4	56.1	58.0	1.08 (0.99, 1.18)	1.11 (1.01, 1.22)
Age (years)	65.3±13.1	65.1±13.2	66.3±12.8	1.01 (1.01, 1.01)	1.02 (1.01, 1.03)
BMI (kg/m^2)[b]	31.6±6.6	31.7±6.6	31.4±6.6	0.91 (0.83, 1.01)	1.00 (0.99, 1.01)
HbA_{1c} (%)[c]	7.9±1.9	7.8±1.9	8.1±2.0	1.07 (1.04, 1.10)	1.12 (1.02, 1.22)
HbA_{1c} (mmol/mol)[c]	63.0	62.0	65.0	-	-
Systolic BP (mmHg)[d]	141.6±20.4	141.3±20.2	142.6±20.7	1.03 (1.01, 1.06)	1.03 (1.01, 1.05)
Diastolic BP (mmHg)[d]	82.6±12.4	82.6±12.3	82.5±12.7	0.99 (0.96, 1.03)	1.02 (0.99, 1.06)
Antihypertensives (%)[e]	70.7	69.6	75.8	1.34 (1.21, 1.49)	1.37 (1.24, 1.52)

Data are mean±SD or proportion (%)

[a] ORs were computed using multiple logistic regression (dependent variable, retinopathy status) including all variables

[b] ORs for BMI are given for obese vs non-obese (BMI >30 kg/m^2)

[c] ORs for HbA_{1c} are given per 1% (11 mmol/mol)

[d] ORs for blood pressure are given per 10 units

[e] ATC: C03, C07, C08, C09

Methods The Disease Analyzer Database (UK) assembles longitudinal data on diagnoses, prescriptions and laboratory values reported from 674 office-based physicians (97 general practices). Patients with newly diagnosed type 2 diabetes (between 2005 and 2009) were identified and the presence of retinopathy was defined based on the International Classification of Diseases code (E11.3) or on the original diagnosis text. The time period between first diabetes diagnosis and first retinopathy diagnosis was calculated. Logistic regression was used to examine associations of potential risk factors with prevalent diabetic retinopathy.
Results There were 12,524 patients with newly diagnosed type 2 diabetes mellitus in the general practices. The mean

BMI (kg/m²)	32.0±6.4	32.2±6.4	31.7±6.4	0.87 (0.82, 0.93)	<0.001
HbA_{1c} (%)	8.1±2.1	8.0±2.1	8.4±2.2	1.07 (1.06, 1.08)	0.001
HbA_{1c} (mmol/mol)	65.0±23.1	63.9±23.1	68.3±24.2	1.06 (1.05, 1.08)	<0.001
Systolic BP (mmHg)	139.9±86.8	139.5±99.6	141.1±24.1		
Diastolic BP (mmHg)	80.9±12	80.9±12.2	81.8±11.4	1.01 (0.98, 1.03)	0.572
Higher socioeconomic status	21,308 (45.2%)	15,993 (45.5%)	3,704 (44.0%)	0.96 (0.91, 1.01)	0.122
Median time to screening (days)	315 (111–607)	305 (109–601)	353 (116–625)	1.12 (1.07–1.17)	<0.001

Data are mean ± SD, median with IQR or frequency with percentage

ORs and *p* values were computed by multiple logistic regression with a model that included all variables

ORs for continuous variables are per ten units except for: HbA_{1c}, which is given per 1% unit (11 mmol/mol); BMI, which is presented for obese vs non-obese; and time to screening, which is presented for screened after 1 year vs screened within 1 year

Methods We identified individuals diagnosed with type 2 diabetes mellitus in Scotland between January 2005 and May 2008 using data from the national diabetes database. We calculated the prevalence of retinopathy and ORs for risk factors associated with retinopathy at first screening.
Results Of the 51,526 people with newly diagnosed type 2 diabetes mellitus identified, 91.4% had been screened by 31 December 2010. The median time to first screening was 315 days (interquartile range [IQR] 111–607 days), but by 2008 the median was 83 days (IQR 51–135 days). The prevalence at first screening of any retinopathy was 19.3%,

Conclusioni

- ✓ **Un approccio personalizzato al diabete è raccomandato dalle linee guida sia in termini di efficacia che di sicurezza.**
- ✓ **Il genere condiziona la prevalenza, l'impatto e la risposta al trattamento dei principali fattori di rischio per le complicanze micro- e macroangiopatiche.**
- ✓ **Le crescenti evidenze sulle interazioni gene-gender e gene-drugs lasciano ipotizzare una loro futura applicazione nella pratica clinica.**
- ✓ **L'integrazione delle informazioni personali, fenotipiche e genetiche consentirà di fare le scelte più appropriate per il singolo individuo con diabete, consentendo di passare da una diabetologia "*personalizzata*" ad una diabetologia di "*precisione*".**

COMMENT

ILLUSTRATION BY GREG CLARKE

Time for one-person trials

Precision medicine requires a different type of clinical trial that focuses on individual, not average, responses to therapy, says **Nicholas J. Schork**.

Every day, millions of people are taking medications that will not help them.

US$215-million national Precision Medicine Initiative. This includes, among other things,

may prescribe one drug for hypertension and monitor its effect on a person's blood pres-

Recognition that physicians need to take individual variability into account is driving huge interest in 'precision' medicine. In January, US President Barack Obama announced a

Studies that focus on a single person — known as *N*-of-1 trials — will be a crucial part of the mix. Physicians have long done these in an ad hoc way. For instance, a doctor

results of many *N*-of-1 trials (all carried out in the same way) will offer information about how to better treat subsets of the population or even the population at large.
