Endocrine, *vol. 23, nos. 2–3, 149–155, March–April 2004*

Table 1
Ideal Candidates for Intracavernous Injection Therapy

Failure of first-line oral therapy
Patient use of nitrates or potential use of nitrates
Neural injury from pelvic surgery, trauma, or radiation
Diabetic patients or severe vasculopaths (often after failed first-line therapy)
Patient desire for rapid onset of erection
Patient desire for greater rigidity and duration of erection than achievable with oral agents

Table 2
Absolute and Relative
Contraindications for Intracavernous Injection Therapy

History of priapism with vasoactive drug use
Severe penile fibrosis
Use of MAOIs (monoamine oxidase inhibitors) which would limit use of phenylephrine for potential priapism
Poor visual acuity limiting needle delivery

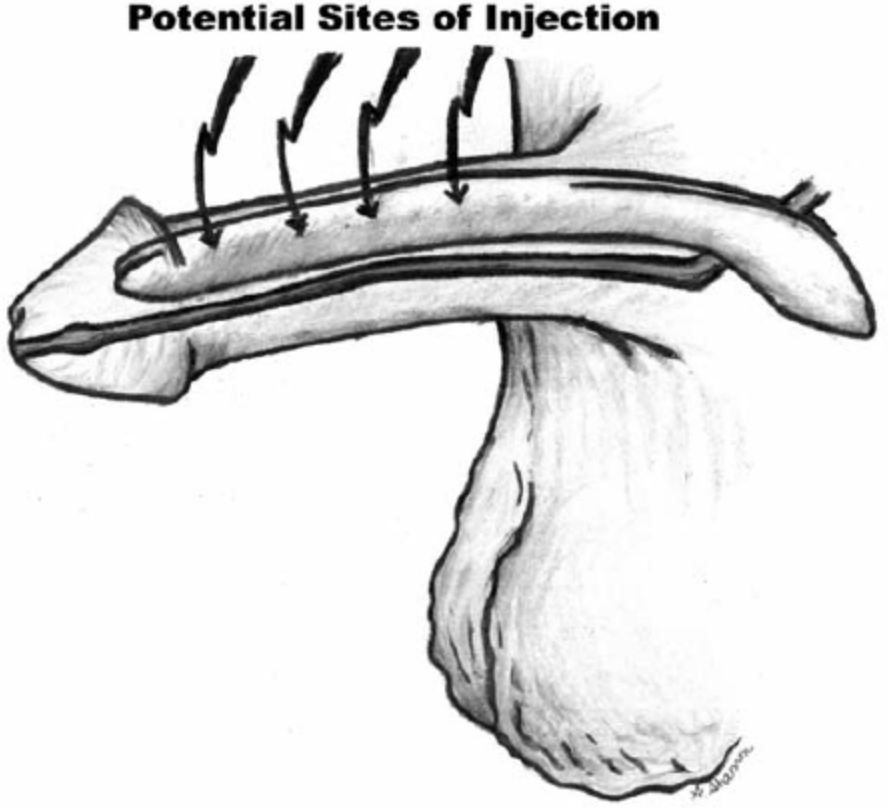

Fig. 2. Sites for intracavernous injection therapy.

Table 3
Strategies to Optimize Intracavernous Injection Therapy

Direct injection into proximal corpora
Gentle local pressure applied to injection site (2–3 min)
Comfortable, stress-free environment
Sexual stimulation following injection
Incremental dose increases if unsuccessful, until recommended dose maximum achieved (minimum 24 h between attempts)
Patient information and support

Endocrine, *vol. 23, nos. 2–3, 149–155, March–April 2004* 0969–711X/04/23:149–155/$25.00

Intracavernous Pharmacotherapy for Erectile Dysfunction

Anthony J. Bella and Gerald B. Brock

Table 4
Inadequate Response
to Intracavernous Injection Therapy: Common Causes

Inadequate dose
Misdirected injection into wrong location (subcutaneous or trabecular)
Leakage of vasoactive agent prior to injection
Inadequate sexual stimulation
Premature ejaculation

Table 5
Common Steps
to Correct Inadequate Therapeutic Response

Reassess dose and increase until therapeutic response achieved
Review of injection technique
Evaluate timing with regards to injection and sexual stimulation
Change to more potent vasoactive agent or combination therapy if at maximum recommended dose
Use combination therapy if pain is limiting factor
Involve partner and reassure

Table 6
Comparison of Single Agent Vs Combination Intracavernous Injection Therapy

Drug	Dose	Efficacy (%)	Priapism > 6 hours (%)	Fibrosis (%)	Drop-out rate (%)
Prostaglandin E-1	12–15 mg (range 5–40 mg)	70–75	1	1–3	40–60
Papaverine	20–80 mg (range 5–160 mg)	55	1–6	6–12	35–50
Phentolamine/papaverine	10 mg/1.25 mg–60 mg/2 mg	70	7	6–12	30–45
Trimix (PGE-1, papaverine, phentolamine)	10 mg/8 mg/0.2 mg–20 mg/20 mg/0.5 mg	75–85	1–3	2–5	25

REVIEW

What is the current role of intracavernosal injection in management of erectile dysfunction?

AI El-Sakka

The emerging of intracavernosal injection (ICI) of vasoactive materials was a major breakthrough in the treatment of erectile dysfunction (ED). However, the current state and future direction of ICI role in the armamentarium of diagnosis, prevention and treatment of ED are not well defined. The aim of this study was to address the current place of ICI in the armamentarium of ED diagnosis and treatment. An English-language MEDLINE review for the utilization of 'intracavernosal injection & erectile dysfunction' was performed from 1990 to present time. Four hundred forty-eight articles were analyzed and classified according to the current utilization of ICI in the following conditions; diagnosis of ED, phosphodiesterase-5 inhibitor (PDE5I) non-responders, diabetes, post radical prostatectomy (RP), stem cells and gene therapy, new intracavernosal drugs, adverse effects and couple satisfaction. This paper is not a standard systematic review; it is eventually a literature review of original peer-reviewed manuscripts and clinical trials reported in Medline. The comprehensive analyses of all the reviewed data were not possible as the level of evidence for utility of ICI in each topic was not available. Current date have established the role of ICI of vasoactive materials as a very common alternative domain in treatment of severe ED particularly in diabetic patients, post-RP, PDE5I non-responders. Further, new studies have denoted the potential future role of intracavernosal treatment for ED in the era of stem cells and gene therapy. ICI of vasoactive material continues to be a highly effective and safe treatment tool for men with wide varieties of ED etiologies. Several experimental and clinical studies are currently investigating new ICI materials. Hopefully in the near future, we might witness evolved molecules and innovative strategies that could help to treat ED patients with different etiologies.

PDE5 inhibitors: targeting erectile dysfunction in diabetics
Sharron H Francis and Jackie D Corbin

Table 1

Emerging and established approaches to improve responsiveness of diabetes-induced erectile dysfunction to PDE5 inhibitor therapy.

- Higher dosing of PDE5 inhibitors and use of different inhibitors
- Education about most effective protocol for use of PDE5 inhibitors
- Increasing PDE5 inhibitor effectiveness by improvement in overall health (decreasing adiposity, improving cardiorespiratory fitness, and controlling hyperglycemia and dyslipidemia)
- Enhancing PDE5 inhibitor effect by normalizing testosterone level
- Chronic daily treatment with PDE5 inhibitors
- Combining PDE5 inhibitor therapy with other therapies

Nei diabetici la prevalenza di DE è maggiore rispetto ai non diabetici.
L'utilizzo corretto dei farmaci a disposizione è fondamentale

% Bound	96	95		94	–
Recommended dose time prior to intercourse (h)	1	0.5–1	1	2	0.5

In summary, PDE5i are a safe and effective treatment for ED in adult men. There are multiple drug options from which the provider and patient may choose to optimise the likelihood of long-term treatment success. While all approved drugs display efficacy, initial drug choice should depend on acomprehensive discussion between provider and patient.

Clinical Practice Guidelines

Can J Diabetes 37 (2013) S150–S152

Erectile Dysfunction

Canadian Diabetes Association Clinical Practice Guidelines Expert Committee

The initial draft of this chapter was prepared by Gerald Brock MD, FRCSC, William Harper MD, FRCPC

RECOMMENDATIONS

1. All adult men with diabetes should be regularly screened for ED with a sexual function history [Grade D, Consensus].

2. Men with diabetes and ED should be investigated for hypogonadism [Grade D, Level 4 (16,31,32,34)].

3. A PDE5 inhibitor, if there are no contraindications to its use, should be offered as first-line therapy to men with diabetes and ED in either an on-demand [Grade A, Level 1A (47-53)] or scheduled-use [Grade B, Level 2 (53,54)] dosing regimen.

4. Referral to a specialist in ED should be considered for eugonadal men who do not respond to PDE5 inhibitors or for whom the use of PDE5 inhibitors is contraindicated [Grade D, Consensus].

5. Men with diabetes and ejaculatory dysfunction who are interested in fertility should be referred to a healthcare professional experienced in the treatment of ejaculatory dysfunction [Grade D, Consensus].

Men with diabetes may require more aggressive treatment for erectile dysfunction

International Journal of Impotence Research (2013) 26, 112–115

TJ Walsh, JM Hotaling, A Smith, C Saigal and H Wessells the Urologic Diseases in America Project

Table 2. Treatment of erectile dysfunction (n) by second- and third-line therapies among men with and without diabetes mellitus

Patient status	N	n	*(%)*	*Odds ratio*	*(95% CI)*
Second-line therapies					
No diabetes	117 070	2134	1.82	1	(ref)
Diabetes	19 236	538	2.80	1.55	(1.408, 1.706)
Third-line therapies					
No diabetes	117 070	437	0.37	1	(ref)
Diabetes	19 236	152	0.79	2.13	(1.77, 2.56)
Second- and third-line combined					
No diabetes	117 070	68	0.06	1	(ref)
Diabetes	19 236	25	0.13	2.24	(1.416, 3.544)

Among a large populationbased cohort of men with ED, those with DM are more likely to require more aggressive treatments. These data suggest that ED among men with diabetes may be less responsive to first-line treatments (oral agents), worsen more rapidly, or both

Sildenafil for Treatment of Erectile Dysfunction in Men With Diabetes

A Randomized Controlled Trial

Marc S. Rendell, MD

JAMA. 1999;281:421-426

Results Two hundred fifty-two patients (94%) completed the study (131/136 in the sildenafil group, 121/132 in the placebo group). By intention-to-treat analysis, at 12 weeks, 74 (56%) of 131 patients in the sildenafil group reported improved erections compared with 13 (10%) of 127 patients in the placebo group ($P<.001$). The proportion of men with at least 1 successful attempt at sexual intercourse was 61% (71/117) for the sildenafil group vs 22% (25/114) for the placebo group ($P<.001$). Adverse events related to treatment were reported for 22 (16%) of 136 patients taking sildenafil and 1 (1%) of 132 patients receiving placebo. The most common adverse events were headache (11% sildenafil, 2% placebo), dyspepsia (9% sildenafil, 0% placebo), and respiratory tract disorder (6% sildenafil, 2% placebo), predominantly sinus congestion or drainage. The incidence of cardiovascular adverse events was comparable for both groups (3% sildenafil, 5% placebo).

Table 4. Incidence of Adverse Events*

Adverse Event	Placebo	Sildenafil Citrate
Headache	2 (2)	15 (11)
Dyspepsia	0 (0)	12 (9)
Respiratory tract disorder	2 (2)	8 (6)
Flushing	0 (0)	6 (4)
Rhinitis	0 (0)	5 (4)
Abnormal vision†	1 (1)	5 (4)

Table 4
Mean scores to Questions 1, 2, and 5 through 15 of the IIEF at baseline and after 16 weeks of treatment with sildenafil or placebo

	Mean score						
	Sildenafil citrate (n = 144)			Placebo (n = 138)			Overall treatment
Question	Baseline	Final[a]	P value	Baseline	Final[a]	P value[b]	P value[c]
1. How often were you able to get an erection during sexual activity?	2.1	3.0 (0.2)	<.002	2.0	2.0 (0.2)	.10	<.002
2. When you had erection with sexual stimulation, how were your erections hard enough for penetration?	1.8	2.9 (0.2)	<.002	1.7	1.9 (0.2)	.82	<.002
5. During sexual intercourse, how difficult was it to maintain your erection to completion of intercourse?	1.4	2.6 (0.2)	<.002	1.3	1.6 (0.2)	.20	<.002
6. How many times have you attempted sexual intercourse?	2.0	3.2 (0.2)	<.001	1.9	2.8 (0.2)	<.001	<.001
7. When you attempted sexual intercourse, how often was it satisfactory for you?	1.7	3.0 (0.3)	<.001	1.6	1.7 (0.3)	.31	<.001
8. How much have you enjoyed sexual intercourse?	1.7	2.7 (0.2)	<.001	1.6	1.8 (0.2)	.53	<.001
9. When you had sexual intercourse, how often did you ejaculate?	2.7	3.7 (0.2)	<.002	2.8	3.3 (0.2)	.50	<.002
10. When you had sexual intercourse, how often did you have the feeling of orgasm or climax?	2.8	3.8 (0.2)	<.002	2.7	3.1 (0.3)	.44	<.003
11. How often have you felt sexual desire?	3.6	3.6 (0.2)	.97	3.5	3.6 (0.2)	.50	.75
12. How would you rate your level of sexual desire?	3.3	3.4 (0.1)	.09	3.3	3.4 (0.1)	.92	.20
13. How satisfied have you been with your overall sex life?	1.8	2.8 (0.2)	<.001	1.8	2.2 (0.2)	.003	<.001
14. How satisfied have you been with your sexual relationship?	2.4	3.2 (0.2)	<.001	2.5	2.8 (0.2)	.03	.002
15. How do you rate your confidence that you could get and keep an erection?	1.7	2.6 (0.2)	<.001	1.6	1.7 (0.2)	.07	<.001

[a] Least squares mean (S.E.) scores.
[b] P values for comparison between baseline and final scores.
[c] P values for overall treatment effect.

Vardenafil, a New Phosphodiesterase Type 5 Inhibitor, in the Treatment of Erectile Dysfunction in Men With Diabetes

IRWIN GOLDSTEIN, MD[1]
JAY M. YOUNG, MD[2]
JEROME FISCHER, MD[3]
KEITH BANGERTER, PHD[4]
THOMAS SEGERSON, MD[4]
TERRY TAYLOR, MD[4]
THE VARDENAFIL DIABETES STUDY GROUP

Diabetes Care 26:777–783, 2003

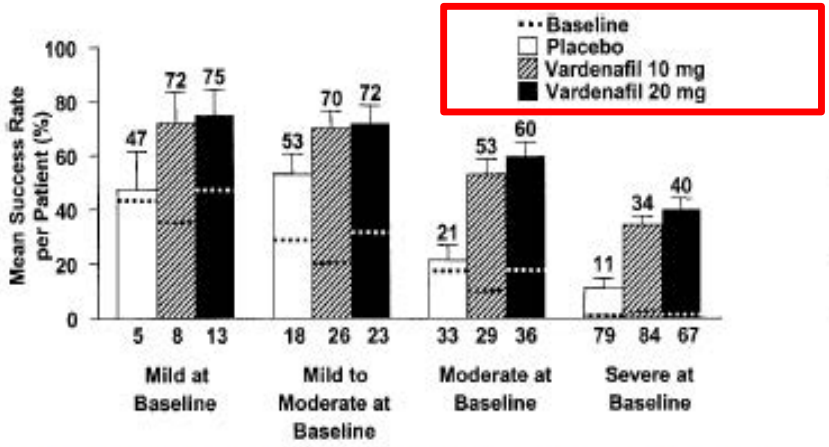

Figure 2—*Efficacy by baseline severity of ED. Rate of successful intercourse ("Did your erection last long enough for you to have successful intercourse?") was determined based on patient baseline ED severity (EF domain scores: mild 22–25, mild to moderate 17–21, moderate 16–11, severe <11) (14). Results presented are the mean (least square) success rates per patient calculated for all attempts over the course of treatment.*

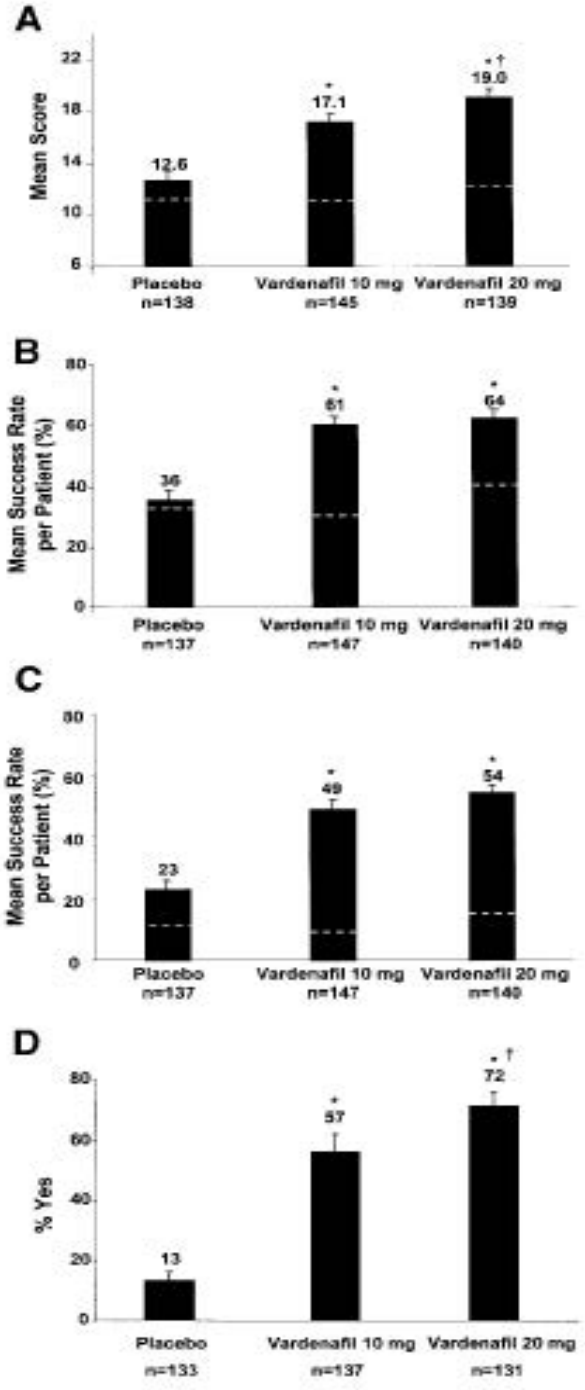

Figure 1—*Primary and secondary efficacy variables. A: EF domain of the IIEF: mean scores (least square) at 12 weeks (LOCF). A score <11 is severe, 11–17 is moderate, 18–25 is mild, and ≥26 is normal. B: Sexual encounter profile (SEP) 2: "Were you able to insert your penis in your partner's vagina?" C: SEP3: "Did your erection last long enough for you to have successful intercourse?" For SEPs, patients recorded their answer ("yes" or "no") in a diary. Results are the mean (least square) per patient value for success rate for all attempts over the course of the 12-week treatment. D: GAQ: "Has the treatment you have been taking over the past 4 weeks improved your erections?" Results are the mean value for patients completing 12 weeks of treatment. Dashed lines represent baseline values. Black bars represent efficacy values after 12 weeks. *P < 0.0001 compared with placebo; †P < 0.03 compared with 10 mg vardenafil.*

Vardenafil 20-mg demonstrated superior efficacy to 10-mg in Japanese men with diabetes mellitus suffering from erectile dysfunction

International Journal of Urology (2006) **13,** 1066–1072

NOBUHISA ISHII,[1] KOICHI NAGAO,[1] KEITA FUJIKAWA,[3] TAKASHI TACHIBANA,[3] YASUHIKO IWAMOTO[2] AND SADAO KAMIDONO[4]

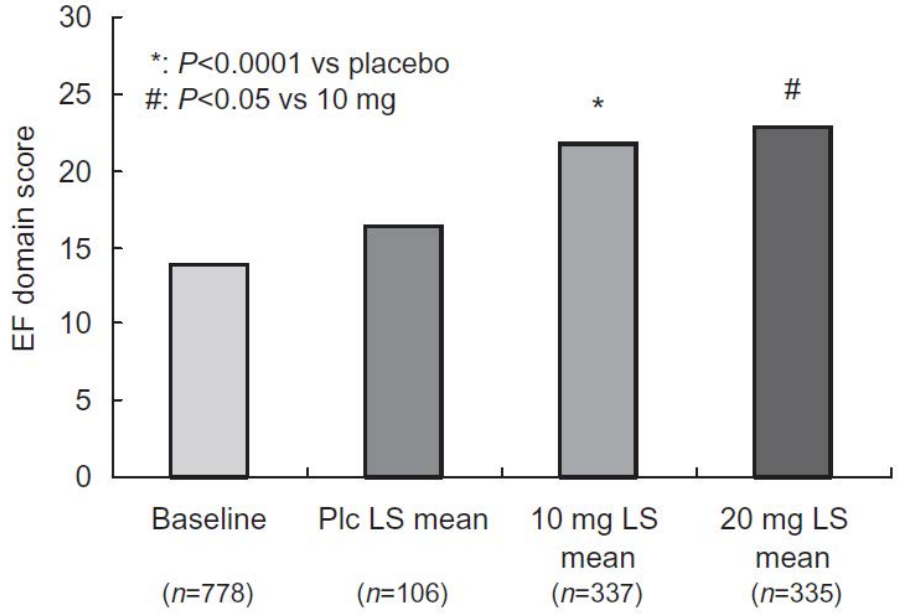

Fig. 2 Vardenafil 10 mg and 20 mg demonstrated significant improvement of IIEF-EF domain score at week 12 (last observation carried forward) compared to placebo. Vardenafil 20 mg demonstrated superior efficacy to 10 mg ($P < 0.05$).

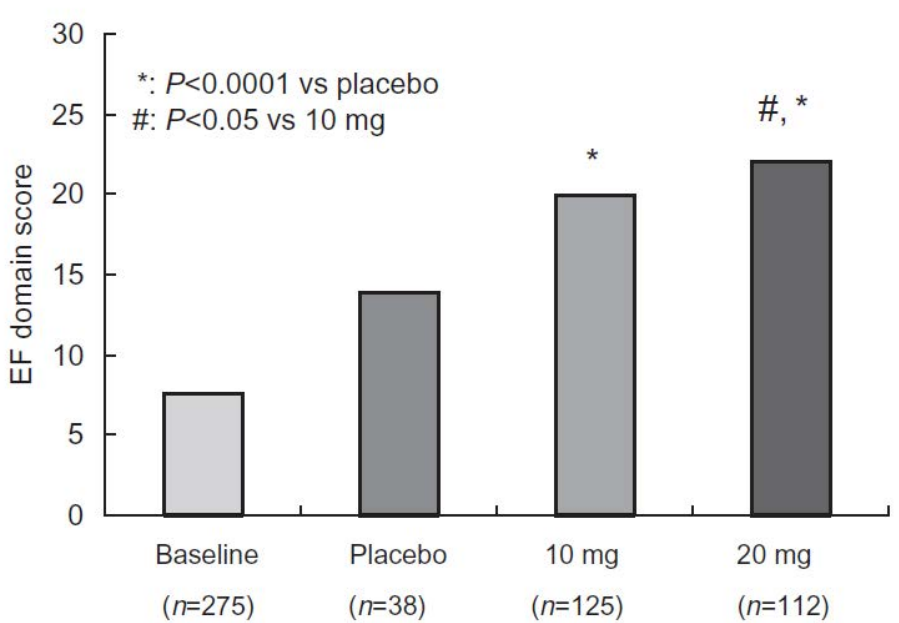

Fig. 3 The difference on efficacy between 10 mg and 20 mg was more evident in severe erectile dysfunction patients (baseline IIEF EF domain score <11).

After 8 weeks of treatment, a significant increase was observed compared with the screening period. After the 4 weeks treatment-free follow-up period, the erectile function domain score decreased significantly in both groups.

Tadalafil in the treatment of erectile dysfunction

Therapeutics and Clinical Risk Management 2008:4(6) 1315–1329

Robert M Coward
Culley C Carson

Division of Urologic Surgery, University of North Carolina, Chapel Hill, NC, USA

Il tadalafil rappresenta un PDE5 inibitore differente rispetto alle altre molecole in commercio:

1. Emivita di 17,5 h negli adulti sani e di 21,6 h negli anziani
2. Finestra terapeutica di circa 36 ore (sono necessarie 48 ore di distanza dall'assunzione di nitrati)
3. Assorbimento non influenzato da pasti grassi e da alcool
4. Possibilità di utilizzo giornaliero (5 mg/die corrispondono ad una concentrazione ematica allo steady state pari ad una somministrazione acuta di 8 mg)
5. T max di 2 h
6. Approvato anche nel trattamento dei disturbi delle vie urinarie inferiori

SAPIENZA
UNIVERSITÀ DI ROMA

Based on these findings, men with diabetes and ED may benefit from daily dosing with PDE5 inhibitors at the onset of treatment, thus leading to an increased therapeutic response with subsequent use. This "priming" phase of therapy could serve to restore or improve endothelial function.

Phosphodiesterase inhibitors for erectile dysfunction in patients with diabetes mellitus (Review)

Cochrane Library
Cochrane Database of Systematic Reviews

Vardi M, Nini A *Cochrane Database of Systematic Reviews* 2007, Issue 1. Art. No.: CD002187.

AUTHORS' CONCLUSIONS

Implications for practice

Sufficient evidence exists that phosphodiesterase type 5 (PDE-5) inhibitors form a care that improves erectile dysfunction in diabetic men.

Implications for research

More research is needed in the following areas:

- assessing the effects of PDE-5 inhibitors in uncontrolled diabetic patients with erectile dysfunction;
- assessing the effects of PDE-5 inhibitors in diabetic women with sexual dysfunction;
- further assessment of the effects of PDE-5 inhibitors on the cardiovascular system in diabetic patients who are prone to coronary arterial disease, and may suffer silent ischemia;
- direct comparisons between the three different available PDE-5 inhibitors;
- direct comparisons between PDE-5 inhibitors and other therapeutic options.

Quali possibilità di trattamento della DE?

a) Utilizzo di un PDE5i orale a breve emivita *on demand;*

b) Utilizzo di tadalafil *on demand;*

c) Utilizzo di tadalafil in cronico (come terapia per la disfunzione endoteliale);

d) Utilizzo di tadalafil in cronico + PDEi a breve emivita *on demand ?!?!*

e) Utilizzo di alprostadil intraureterale (Vitaros ™) o per uso intracavernoso (Caverject ™)

Attualmente sono disponibili diverse opzioni farmacologiche per la DE; al clinico va la capacità di operare le scelte più opportune

Quali possibilità di trattamento della DE?

a) Sildenafil (disponibile come farmaco generico) 50 mg e 100 mg; 50 mg Viagra ™ ORO (orosolubile)
b) Vardenafil (Levitra ™)5mg, 10 mg e 20 mg (10 mg anche in versione orosolubile)
c) Avanafil (Spedra ™) 100 mg e 200 mg
d) Tadalafil (Cialis ™) 5mg (approvato per uso cronico), 10 mg e 20 mg
e) Alprostadil intrauretrale (Vitaros ™) 2 mg/g e 3 mg/g
f) Alprostadil intracavernoso (Caverject ™) 10 mcg e 20 mcg

Nella primavera del 2018 sarà disponibilie in formulazione generica anche il tadalafil

Nuova formulazione di sildenafil in film orodispersibile (ODF's) brevettata da IBSA Farmaceutici

Disponibili in 4 dosaggi: 25mg-50mg-75mg-100mg
Saranno disponibili 3 confezioni: da 2,4 e 8 film In commercio da metà Maggio.
Vantaggi della nuova formulazione:
-Migliore aderenza terapeutica
-Comodità e discrezione nell'assunzione, facilmente trasportabile
-Assunzione senz'acqua
-Dissoluzione rapida in pochi secondi
-Dosaggio preciso e uniforme
-Pochi eccipienti (e allergeni): polimero filmante idrosolubile(maltodestrine), plasticizzante, colorante ed aroma
Primi dati di utilizzo suggeriscono una maggiore biodisponibilità se assunto a livello sublinguale limitando al tempo stesso gli effetti indesiderati rispetto alle formulazioni in uso attualmente (compresse e compresse orodispersibili).

Sexual Dysfunction in Type 2 Diabetes at Diagnosis: Progression over Time and Drug and Non-Drug Correlated Factors

Giovanni Corona[1]*, Carlo B. Giorda[2], Domenico Cucinotta[3], Piero Guida[4], Elisa Nada[5], SUBITO-DE Study Group[¶]

PLOS ONE | DOI:10.1371/journal.pone.0157915 October 5, 2016

Table 2. Prevalence of erectile dysfunction (ED) severity based on the International Index of Erectile Function (IIEF) short version score (No ED >21; Mild ED 17–21, Mild-moderate ED 12–16, Moderate ED 8–11, severe ED <8) at baseline (phase 1) and follow-up assessment (phase 2) in the whole study population and after excluding subjects who reported no sexual activity.

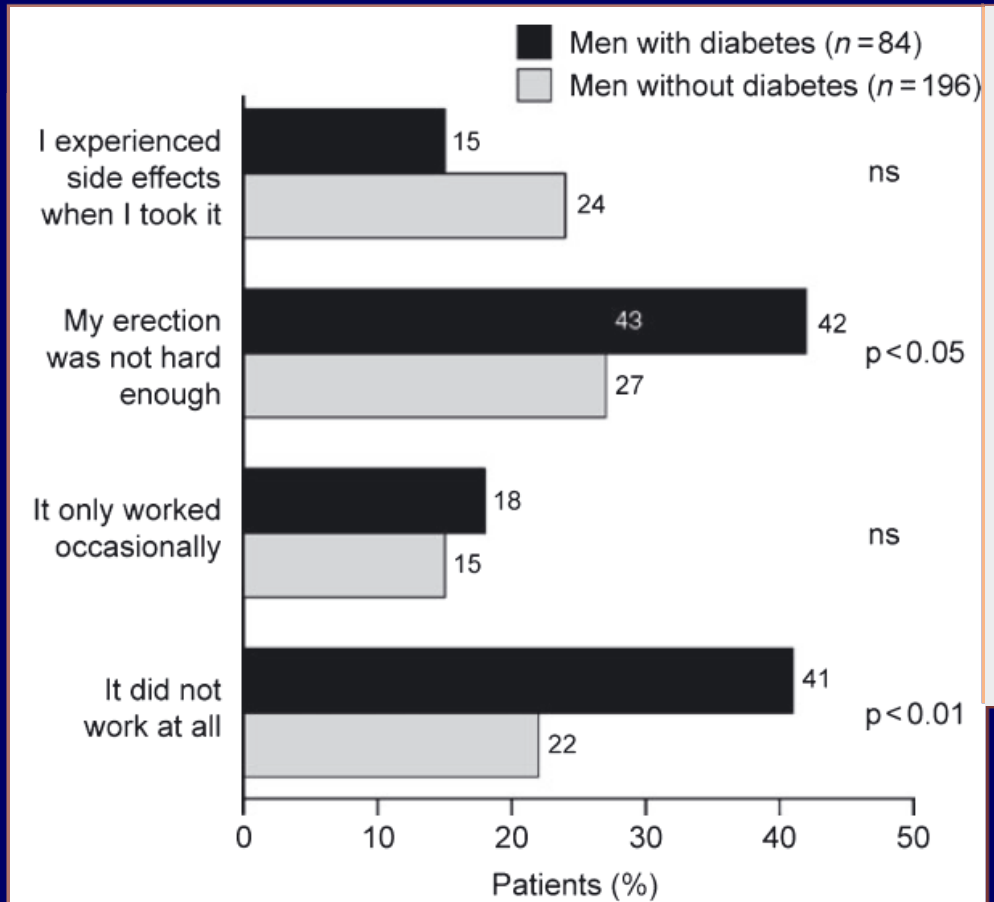
Whole study population	Phase 1 n (%)	Phase 2 n (%)
No sexual activity	82 (18.2)	65 (14.4)
Severe ED	20 (4.4)	14 (3.1)
Moderate ED	41 (9.1)	33 (7.3)
Mild-Moderate ED	68 (15.1)	55 (12.2)
Mild ED	89 (19.8)	87 (19.3)
No ED	150 (33.3)	196 (43.6)
Total	450	450
Excluding subjects who reported no sexual activity	**Phase 1 n (%)**	**Phase 2 n (%)**
Severe ED	18 (5.2)	11 (3.2)
Moderate ED	39 (11.2)	29 (8.3)
Mild-Moderate ED	64 (18.3)	51 (14.6)
Mild ED	84 (24.1)	77 (22.1)
No ED	144 (41.3)	181 (51.9)
Overall ED improvement	-	102 (29.2)*
Overall ED worsening	-	58 (14.9)
Total	349	349

…sexual function is a major concern for men with T2DM. The SUBITO-DE study provides evidence that, when combined with adequate counseling and a tailored PDE5i therapy, an integrated approach to helping men with recently diagnosedT2DM achieve their metabolic targets may also improve sexual function and depressive symptoms.

The multinational Men's Attitudes to Life Events and Sexuality study: the influence of diabetes on self-reported erectile function, attitudes and treatment-seeking patterns in men with erectile dysfunction

Int J Clin Pract, September 2007, **61**, 9, 1446-

I. Eardley,[1] W. Fisher,[2] R. C. Rosen,[3] C. Niederberger,[4] A. Nadel,[5] M. Sand[6]



What's new

The prevalence of ED is greater in men with diabetes compared with those without. The cardiovascular associations of ED are confirmed. Men with diabetes are more likely to consider their ED as severe and permanent, more likely to discuss their condition with a healthcare professional, and more likely to have filled a prescription for an oral PDE5 inhibitor. Discontinuation rates are high, however, because of a perceived lack of efficacy.

Time for one-person trials

Precision medicine requires a different type of clinical trial that focuses on individual, not average, responses to therapy, says **Nicholas J. Schork**.

Muammer Kendirci Curr Opin Urol 16:449–459. © 2006

Table 1 Success and failure rates of sildenafil therapy in men with erectile dysfunction and concomitant risk factors

Risk factors	Per cent success (more than 75% of attempts)	Per cent failure
Neurological disease	85	15
Hypogonadism with testosterone replacement therapy (TRT)	85	15
Alcohol abuse	85	15
Hypogonadism without TRT	75	9
Hypertension	83	17
Smoking	80	20
Multiple medications	77	23
Asthma	76	24
Penile fibrosis	75	25
Asymptomatic coronary artery disease	71	29
Hypertension with diabetes	65	35
Diabetes	63	37
Peripheral vascular disease	63	37
Transurethral resection of the prostate	60	40
Diabetes with neuropathy	50	50
Uncontrolled diabetes	44	56
Postradical prostatectomy	43	57

The role of pharmacokinetics and pharmacodynamics in phosphodiesterase-5 inhibitor therapy

International Journal of Impotence Research (2007) 19, 253–264

Table 3 Contraindications and dose adjustments for PDE5 inhibitors[15,42]

Pharmacodynamic interactions

Contraindications

- *Nitrates*: concomitant use of PDE5 inhibitors with nitrates is absolutely contraindicated as they potentiate the hypotensive effects of nitrates

REVIEW N Mehrotra[1], M Gupta[2], A Kovar[3] and B Meibohm[1]

The role of pharmacokinetics and pharmacodynamics in phosphodiesterase-5 inhibitor therapy

International Journal of Impotence Research (2007) 19, 253–264

Pharmacokinetic interactions

Concomitant medications potentially requiring lower doses of PDE5 inhibitors or administering them with caution

- Ketoconazole
- Itraconazole
- Erythromycin
- Clarithromycin
- HIV protease inhibitors (ritonavir, saquinavir and indinavir): Ritonavir has an unusually high effect on systemic exposure of vardenafil, and 50% dose reduction is warranted
- Grapefruit juice
- Cimetidine
- Antacids: tadalafil's rate of absorption decreased by 30%; no interaction with sildenafil or vardenafil

Concomitant medications potentially requiring higher doses of PDE5 inhibitors

- Rifampin
- Phenobarbital
- Phenytoin
- Carbamazepin

European Association of Urology 2015

MALE SEXUAL DYSFUNCTION - UPDATE MARCH 2015

3A.4.5.1.7.4 α-Blocker interactions

All PDE5Is show some interaction with α-blockers, which under some conditions may result in orthostatic hypotension.

- Sildenafil labelling advises that 50 or 100 mg sildenafil should be used with caution in patients taking an α-blocker (especially doxazosin). Hypotension is more likely to occur within 4 h following treatment with an α-blocker. A starting dose of 25 mg is recommended [99].
- Concomitant treatment with vardenafil should only be initiated if the patient has been stabilised on his α-blocker therapy. Co-administration of vardenafil with tamsulosin is not associated with clinically significant hypotension [102-104].
- Tadalafil is not recommended in patients taking doxazosin, but this is not the case for tamsulosin [101, 118].
- Avanafil labelling currently reports that patients should be stable on α-blocker therapy prior to initiating avanafil. In these patients, avanafil should be initiated at the lowest dose of 50 mg. Conversely, in those patients already taking an optimised dose of avanafil, α-blocker therapy should be initiated at the lowest dose.

Koji Mita

Women's perception of male erectile dysfunction drugs in the general population

Hiroshima, Japan

Maturitas 56 (2007) 216–222

***1262 women*, 20-77 yrs old ,participated.**

83.3% were aware of the existence of ED drugs, but only 12.0% showed some interest in them,

46.4% and 43.2% of the participants claimed to have an unfavorable image of ED drugs, and of men using ED drugs, respectively.

45.2% stated that if their partners suffered from ED at present or in the future, they would not desire their partners to use ED drugs, and 25.5% stated that they would not accept it.

Assessing satisfaction in men and their female partners after treatment with phosphodiesterase type 5 inhibitors for erectile dysfunction

Table 2. Percentage of patients presenting deviation in the semistructured interview covering 6 main topics related to PDE5i poor response

Question	Percentage
1. Did you have adequate sexual stimulation?	3.2
2. Did you try at least six different days?	32.8
3. Did you reach the maximum dose at which the drug can be administered?	30.8
4. Did you have an empty stomach and/or had ingested alcohol prior to the intake of the drug (except for tadalafil)?	21.6
5. Did you wait at least 1 hour if taking sildenafil or vardenafil and 2 hours in case of tadalafil before initiating the sexual relationship?	17.2
6. Have you tried at least two different types of PDE5i?	40.8

Why Don't Healthcare Professionals Talk About Sex? A Systematic Review of Recent Qualitative Studies Conducted in the United Kingdom

Kerry Dyer

J Sex Med 2013;10:2658

Nineteen interconnected themes emerged relating to healthcare professionals' experience of discussing sexuality with service users, including fear about "opening up a can of worms," lack of time, resources, and training, concern about knowledge and abilities, worry about causing offense, personal discomfort, and a lack of awareness about sexual issues.

The majority of healthcare professionals do not proactively discuss sexuality issues with service users.

Management of Erectile Dysfunction in General Practice

Giorgia De Berardis J Sex Med 2009;6:1127–1134.

Only 9.6% of the GPs reported routinely inquiring about ED of men older than 40 years of age,

45.2% did investigate the presence of ED in patients with identifiable risk factors;

45.2% of the respondents reported inquiring about ED only when the patient raised the problem.

General Practitioners' Procedures for Sexual History Taking and Treating Sexual Dysfunction in Primary Care

J Sex Med 2014;11:386–393

Sofia Ribeiro, MD,* Violeta Alarcão, D. Sociol.,* Rui Simões, MSc,* Filipe Leão Miranda, MA,* Mário Carreira, MD,* and Alberto Galvão-Teles, PhD*†

Results. Of the 50 participants (73.5% response rate), 15.5% actively ask their patients about SD. The main reasons for asking patients about their sexuality are diabetes (84.0%), prescription of medication with adverse effects on sexuality (78.0%), and family planning (72.0%), the latter being a significantly more frequent reason for GPs with 20 or less years of practice. Routine sexual history taking (22.0%) appears as one of the least mentioned motives. The percentage of appointments with active exploration of SD was positively associated with guidelines' consultation, as well as considering the specialty as a good source of information and having longer appointments when SD is mentioned. However, 76.0% report not having consulted any guidelines in the previous year. Lack of time (31.6%) and low accessibility (25.0%) were referred to as the main reasons for not consulting guidelines.

Conclusions. Routine sexual history taking and consultation of guidelines about SD are not yet a generalized practice in primary care.
Data should be interpreted with caution as they are self-reported.
Further objective measurement such as direct observation or clinical files consultation should be implemented.

Trattamento polifarmacologico nei pazienti diabetici

Buona parte dei pazienti diabetici affetti da disfunzione erettile assume diversi altri farmaci per condizioni patologiche interconnesse alla patologia diabetica quali, ad esempio, ipertensione, cardiopatia, dislipidemia, ecc

I farmaci assunti per tale patologie possono avere effetti positivi o negativi sulla DE. Al curante spetta pertanto la scelta corretta in tal senso

Trattamento polifarmacologico nei pazienti diabetici

- *ipertensione;*
- *insufficienza cardiaca;*
- *dislipidemia;*

Table 7 Drugs that may contribute to ED [23,25]

Class	Individual agents
Diuretics	Thiazides
	Spironolactone
Antihypertensives	Methyldopa
	Clonidine
	Reserpine
	Beta-blockers
	Guanethidine
	Verapamil
Cardiac/circulatory	Clofibrate

A new potential risk factor in patients with erectile dysfunction and premature ejaculation: folate deficiency

Wen-Jie Yan*, Nan Yu*, Tai-Lang Yin, Yu-Jie Zou, Jing Yang

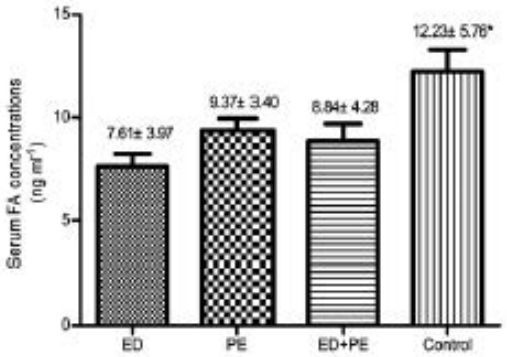

Figure 1: Serum folic acid (FA) concentrations in patients with sexual dysfunctions and in control participants. The bars show the average serum FA concentration in each group. *Significantly higher FA levels.

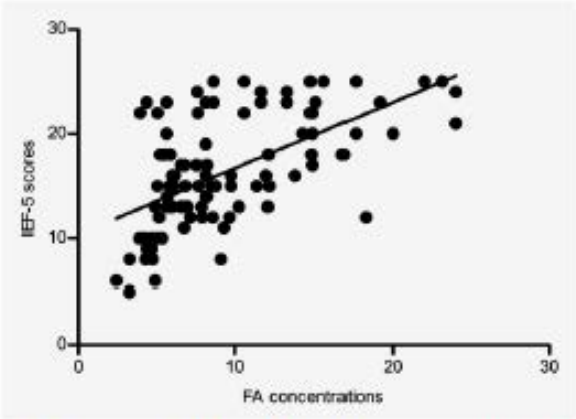

Figure 2: Correlation between International Index of Erectile Function-5 scores and folic acid concentrations. The scatter diagram shows that the correlation coefficient (r) is 0.589, $P < 0.01$.

A role for folate?

Table 2: Correlation coefficients of FA concentrations with clinical parameters

	FA (r)	*P*
Age	0.096	0.271
BMI	–0.142	0.104
LH	0.052	0.551
FSH	–0.110	0.209
Total T	0.134	0.124
IELT	0.445	<0.01
Hcys	–0.508	<0.01
CIPE score	0.530	<0.01
IIEF-5 score	0.589	<0.01

BMI: body mass index; FSH: follicle-stimulating hormone; LH: luteinizing hormone; Total T: total testosterone; Hcys: homocysteine; IELT: intravaginal ejaculation latency time; CIPE: Chinese Index of Premature Ejaculation; IIEF-5: International Index of Erectile Function-5; FA: folic acid

A role for folate?

Nebivolol Potentiates the Efficacy of PDE5 Inhibitors to Relax Corpus Cavernosum and Penile Arteries from Diabetic Patients by Enhancing the NO/cGMP Pathway

Martínez-Salamanca et al. J Sex Med 2014;11:1182-

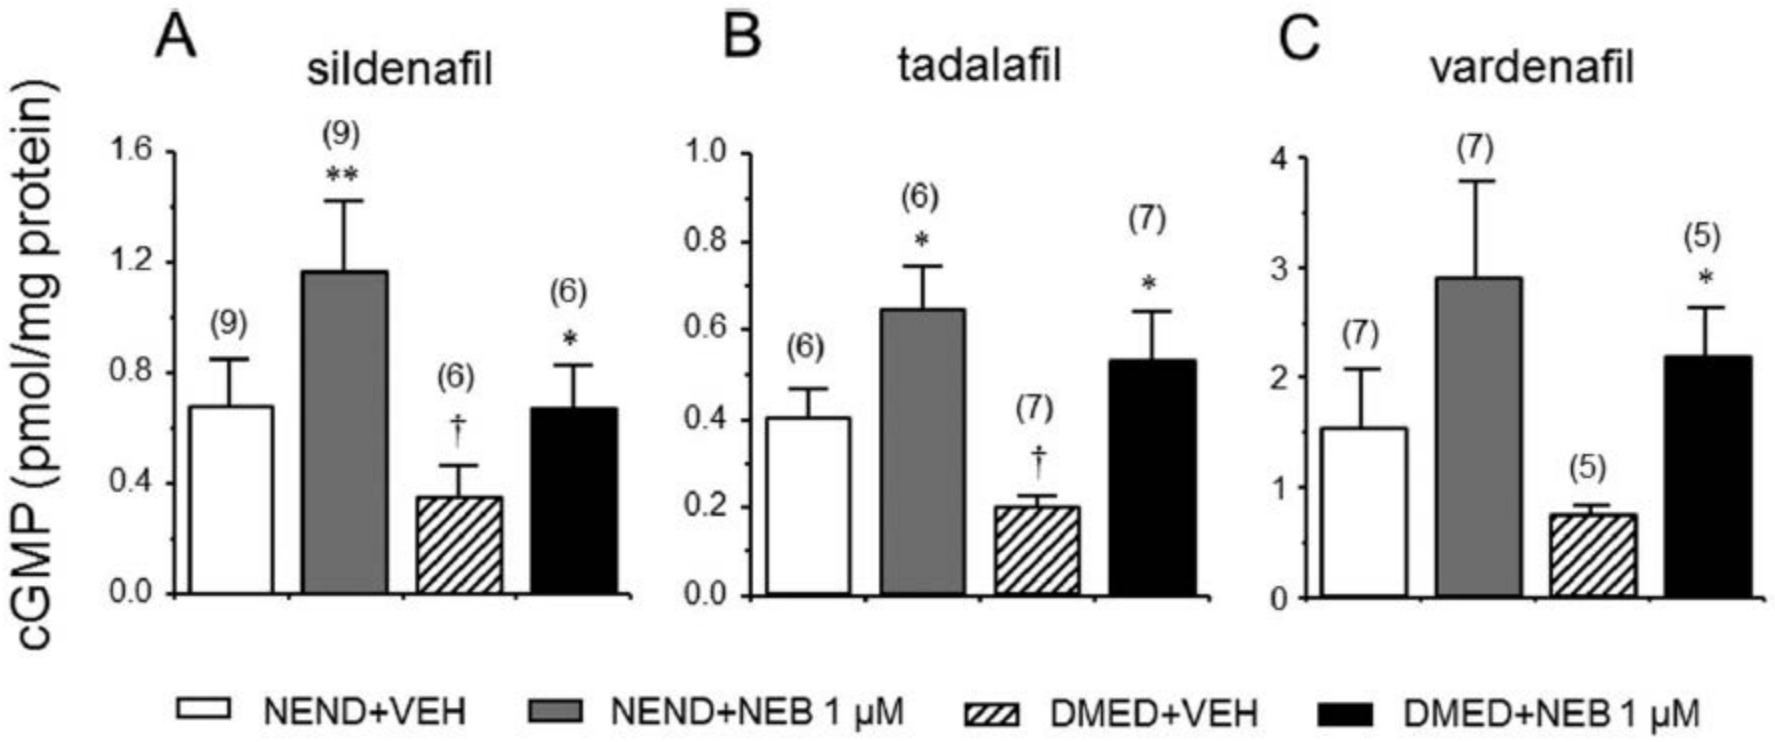

Figure 4 Nebivolol increases cGMP accumulation induced by PDE5 inhibitors in human corpus cavernosum from diabetic patients with ED.

Effects of nebivolol (NEB; 1 μM) or vehicle (VEH; 0.01% DMSO) on cGMP accumulation induced by the PDE5 inhibitors (10 μM), sildenafil (A), tadalafil (B), and vardenafil (C), in human corpus cavernousm from organ donors without a history of diabetes or ED (NEND) and from diabetic patients with ED (DMED). Data are expressed as mean±SEM of pmoles of cGMP per milligram of tissue protein. n indicates the number of patients from whom the tissues were collected. $^{*}P < 0.05$, $^{**}P < 0.01$ vs. vehicle, †$P < 0.05$ vs. NEND by one-factor ANOVA followed by Student-Newmann-Keuls test.

The problem of multiple drugs and the subjective factor in DM
