DOTTORE HO UNA BELLA NOTIZIA…

CGM per tutte?

Sara Belcastro, MD, PhD

AOU Città della Salute e della Scienza di Torino

Dichiarazione Conflitto d'Interessi

La sottoscritta Dott.ssa Sara Belcastro
DICHIARA
di aver ricevuto negli ultimi due anni compensi o finanziamenti dalle seguenti Aziende Farmaceutiche e/o Diagnostiche:

- Novo Nordisk
- Lilly
- Roche
- Boeringher

Dichiara altresì il proprio impegno ad astenersi, nell'ambito dell'evento, dal nominare, in qualsivoglia modo o forma, aziende farmaceutiche e/o denominazione commerciale e di non fare pubblicità di qualsiasi tipo relativamente a specifici prodotti di interesse sanitario (farmaci, strumenti, dispositivi medico-chirurgici, ecc.)

POSITION STATEMENT

The use of technology in diabetes in pregnancy: a position statement of expert opinion from the association of medical diabetologists (AMD), the Italian society of diabetology (SID) and the interassociative diabetes and pregnancy study group

Veronica Resi[1] · Cristina Bianchi[2] · Silvia Burlina[3] · Valeria Grancini[1] · Elisa Manicardi[4] · Maria Masulli[5] · Antonietta Maria Scarpitta[6] · Gian Pio Sorice[7] · Raffaella Fresa[8]

Received: 4 July 2025 / Accepted: 20 September 2025

Table 1 Glycemic targets in pregnancy by national and international guidelines

	SID-AMD [9]	ADA [6]		ACOG [10]	NICE [11]
		T1D or T2D and GDM insulin treated	GDM not insulin treated		
Fasting (mg/dL)	≤90	70–95*	<95	70–95	≤95^
1 h post-prandial (mg/dL)	≤130	110–140	<140	110–140	≤140
2 h post-prandial (mg/dL)	≤120	100–120	<120	100–120	≤115

*Lower glucose limits do not apply to individuals with type 2 diabetes treated with nutrition alone

^For women on insulin therapy, the minimum capillary glucose value is 72 mg/dL

Self Blood Glucose Monitoring in pregnancy

SBGM

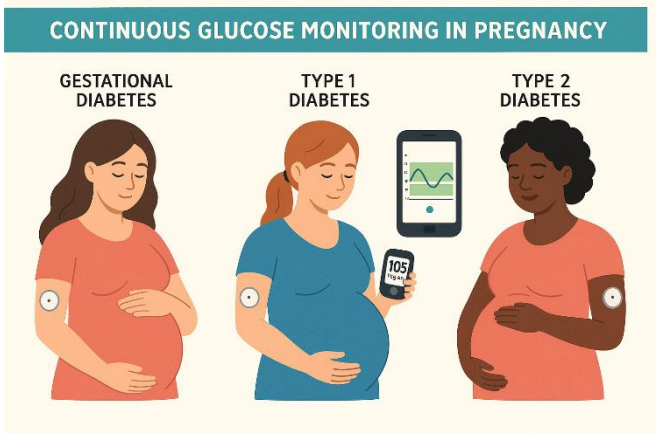
The **2018 Italian Standards for Diabetes Care** recommend <u>frequent SBGM for pregnant women</u>:

- For women undergoing dietary management: 75 measurements/month are suggested/recommended;

- For women on insulin therapy: 100–250 measurements/ month are suggested/recommended, depending on clinical circumstances.

Glucose Continuous Monitoring in pregnancy

CGM



- very useful for both the patient and the clinician in analysing **daily glucose trends** and making adjustments to **ongoing** insulin therapy;
- Is-CGM systems are also approved for use in pregnancy, but caution is advised because they report *longer* times below range (% TBR (<63 mg/dL) compared with rt-CGM, especially overnight, in pregnant women with T1D.

Resi V. et al Acta diabetologica 2025
https://doi.org/10.1007/s00592-025-02592-2

SBGM vs CGM

Aspect	SMBG	CGM
Measurement Type	Single-point glucose snapshots	Continuous glucose data (24/7)
Trend Information	*Not available*	Provides **trends** and rate of change
Detection of Hypo/Hyperglycaemia	Limited to the moment of testing	Real-time detection, **alarms available**
User Burden	Requires multiple daily fingersticks	Less frequent calibration and manual intervention
Patient Adherence	Often poor due to repeated checks	Generally better adherence
Glycaemic Metrics	Basic values (pre/post meals)	Time in Range, variability, patterns
Clinical Decision Support	Limited	Stronger support due to richer data
Cost	**Low**	Higher
Reimbursement (Italy)	**Uniformly** reimbursed by SSN	Variable across regions
Ease of Use	Simple but invasive	Easy to use, **minimally invasive**
Limitations	No trends, snapshot only	Sensor cost, regional reimbursement variability

Resi V. et al Acta diabetologica 2025
https://doi.org/10.1007/s00592-025-02592-2

Clinical CGM targets for assessment of glycemic control during pregnancy

Table 3 Target values for continuous glucose monitoring [30]

	Time in range (TIR) (63–140 mg/dl)	Time above range (TAR) (>140 mg/dl)	Time below range (TBR) (<63 mg/dl)	Time below range (TBR) (<54 mg/dl)
Type 1 diabetes	>70% (>16 h 48 min/day)	<25% (<6 h/day)	<4% (<1 h/day)	<1% (15 min/day)
Type 2 diabetes^	≥90%	<5%	<4%	<1%

^For T1D target values are recommended, for T2D target values are suggested

Remember to set correct metrics on a CGM in pregnancy!

HbA1c

HbA1c in pregnancy

In pregnancy → RBC turnover, iron deficiency/supplementation, alteration of plasma proteins, rapid change in metabolic compensation

In addition, because HbA1c is an average of glucose levels, **it may not adequately reflect postprandial hyperglycemia**, which is associated with outcomes such as macrosomia.

Therefore, HbA1c is used as a ***secondary measure*** of glycemic outcomes in pregnancy (*only* in DMT1).

HbA1c target is <6 –6.5% (42–48 mmol/mol); lower HbA1c—6% (42 mmol/mol) is optimal if it can be achieved **without significant hypoglycemia**.

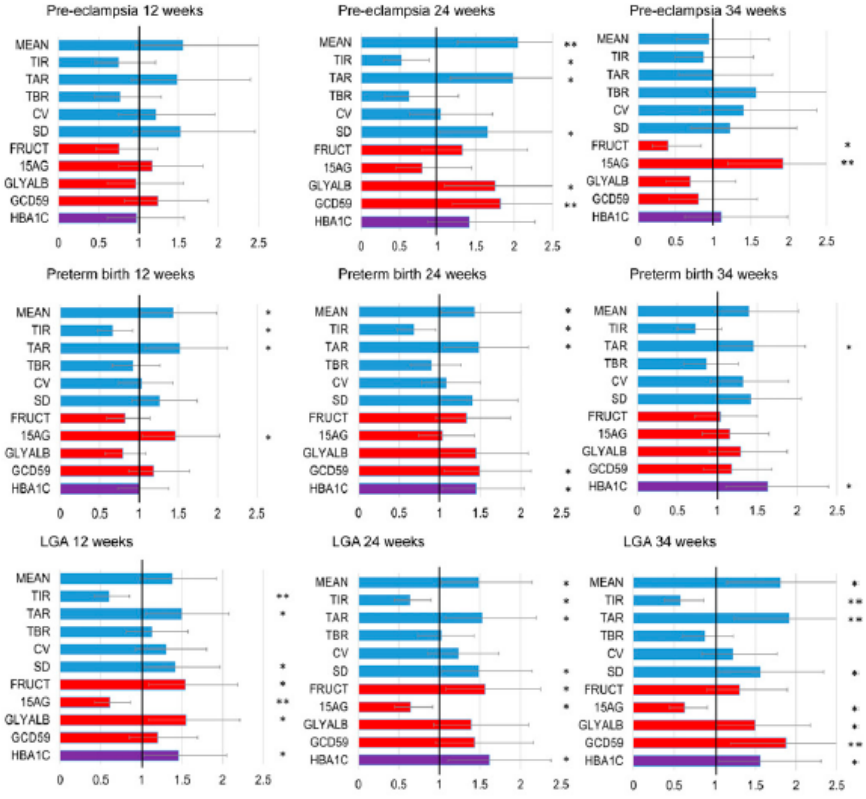
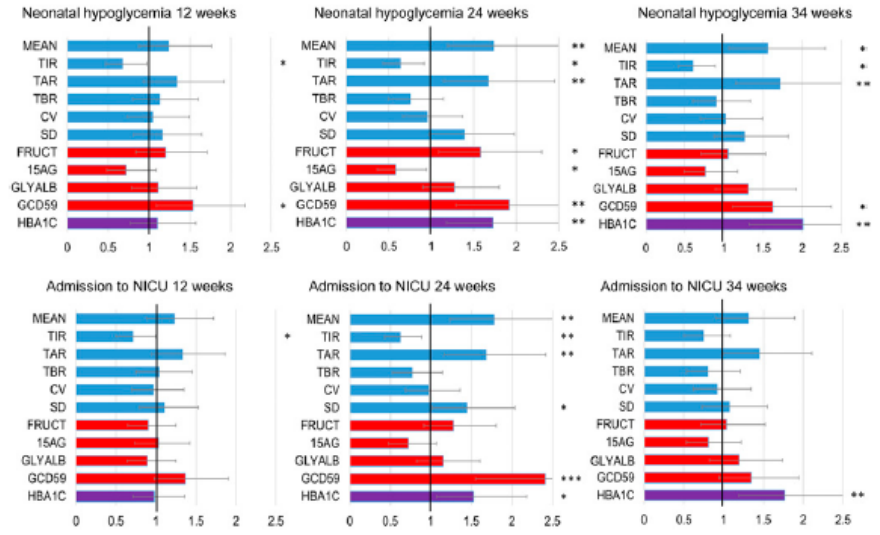
CGM metrics in pregnant women with DMT1 and clinical outcomes

The CONCEPTT study





- ✓ HbA_{1c} is still an **important biomarker** for obstetric and neonatal outcomes in type 1 diabetes pregnancy.
- ✓ Other CGM metrics **did not** substantially increase the prediction of pregnancy outcomes compared with widely available HbA_{1c}, TIR and TAR.

Meek CL. Diabetes Care 2021;44(3):681-689

Accuracy of GMI and pregnancy outcomes in type 1 diabetes

- The CONCEPTT study -

Example:
HbA_{1c} 8.1% Conception
GMI: 8.4% 12 weeks
GMI: 7.7% 20 weeks
GMI: 7.6% 36 weeks

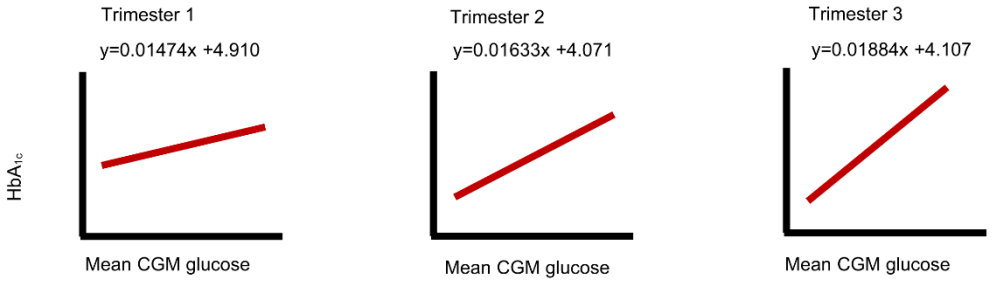
Existing evidence suggests:

50% GMI values show ≥0.5% error (bias) in HbA_{1c} assessment.

These changes may be due to chance alone.

Bias rates in pregnancy are highest in 1st and 3rd trimester.

Would pregnancy-specific equations help?
Relationship between mean CGM glucose and HbA_{1c} changes in each trimester.



Glucose monitoring options most strongly associated with outcomes in pregnancy

CGM
TIR
TAR
~~GMI~~

HbA_{1c}

GMI:
- Less accurate in pregnancy
- Many changes due to chance alone
- Offers no prognostic benefit over other options
- Potentially misleading

The Effect of Real-Time Continuous Glucose Monitoring in Pregnant Women With Diabetes

A randomized controlled trial

Peter Damm, md, dmsc[1,3,5]
Elisabeth R. Mathiesen, md, dmsc[1,2,3]

OBJECTIVE—To assess whether intermittent real-time continuous glucose monitoring (CGM) improves glycemic control and pregnancy outcome in unselected women with pregestational diabetes.

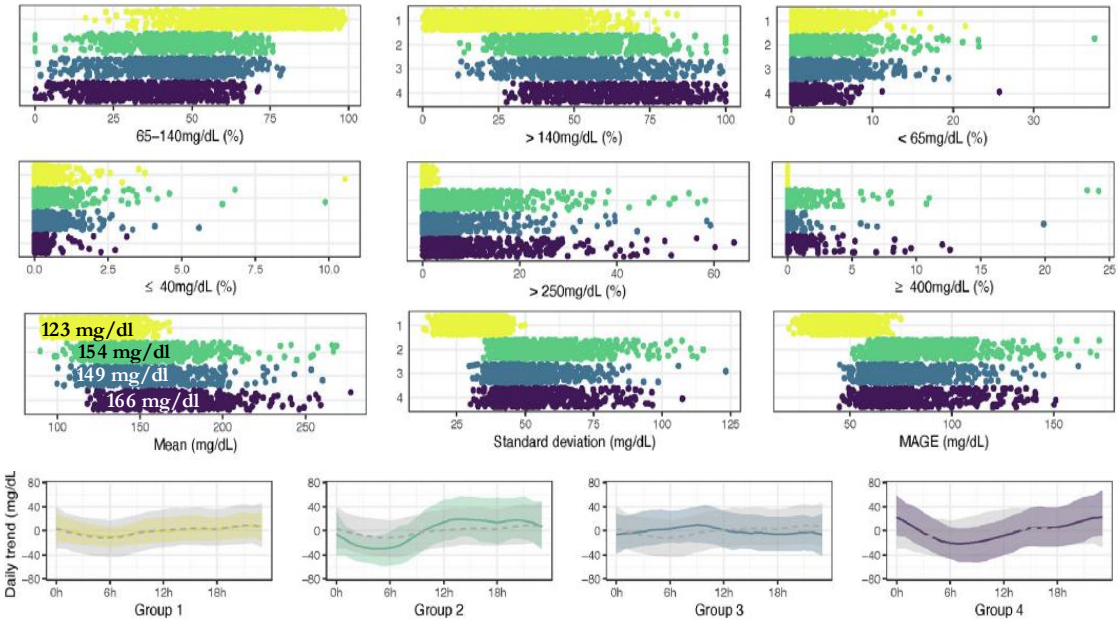
RESEARCH DESIGN AND METHODS—A total of 123 women with type 1 diabetes and 31 women with type 2 diabetes were randomized to use real-time CGM for 6 days at 8, 12, 21, 27, and 33 weeks in addition to routine care, including self-monitored plasma glucose seven times daily, or routine care only. To optimize glycemic control, real-time CGM readings were evaluated by a diabetes caregiver. HbA_{1c}, self-monitored plasma glucose, severe hypoglycemia, and pregnancy outcomes were recorded, with large-for-gestational-age infants as the primary outcome.

RESULTS—Women assigned to real-time CGM ($n = 79$) had baseline HbA_{1c} similar to that of women in the control arm ($n = 75$) (median 6.6 [range 5.3–10.0] vs. 6.8% [5.3–10.7]; $P = 0.67$) (49 [34–86] vs. 51 mmol/mol [34–93]). Forty-nine (64%) women used real-time CGM per protocol. At 33 weeks, HbA_{1c} (6.1 [5.1–7.8] vs. 6.1% [4.8–8.2]; $P = 0.39$) (43 [32–62] vs. 43 mmol/mol [29–66]) and self-monitored plasma glucose (6.2 [4.7–7.9] vs. 6.2 mmol/L [4.9–7.9]; $P = 0.64$) were comparable regardless of real-time CGM use, and a similar fraction of women had experienced severe hypoglycemia (16 vs. 16%; $P = 0.91$). The prevalence of large-for-gestational-age infants (45 vs. 34%; $P = 0.19$) and other perinatal outcomes were comparable between the arms.

CONCLUSIONS—In this randomized trial, intermittent use of real-time CGM in pregnancy, in addition to self-monitored plasma glucose seven times daily, did not improve glycemic control or pregnancy outcome in women with pregestational diabetes.

Glucose profiles identified using CGM in pre-gestational diabetes during pregnancy

Retrospective cohort study	Since January 2019 up to August 2023	175 pregnant women using CGM • Type 1 diabetes: 90 • Type 2 diabetes: 85	Glucose profiles based on weekly CGM metrics



Well controlled

Suboptimally controlled with high variability, fasting hypoglycemia, and daytime hyperglycemia

Suboptimally controlled with minimal circadian variation

Poorly controlled with peak hyperglycemia overnight

Battarbee AN. Am J Obstet Gynecol 2024;231(1):122.e1-122.e9

CGM in pregnant women with DMT1 and DMT2

The role and use of CGM is **well established in type 1 diabetes** also may be considered in women with T2D treated with MDI, both during pregnancy planning and during pregnancy to improve glycaemic control.

CGM may also facilitate follow-up via telemedicine where appropriate, thereby increasing patient engagement in diabetes care.

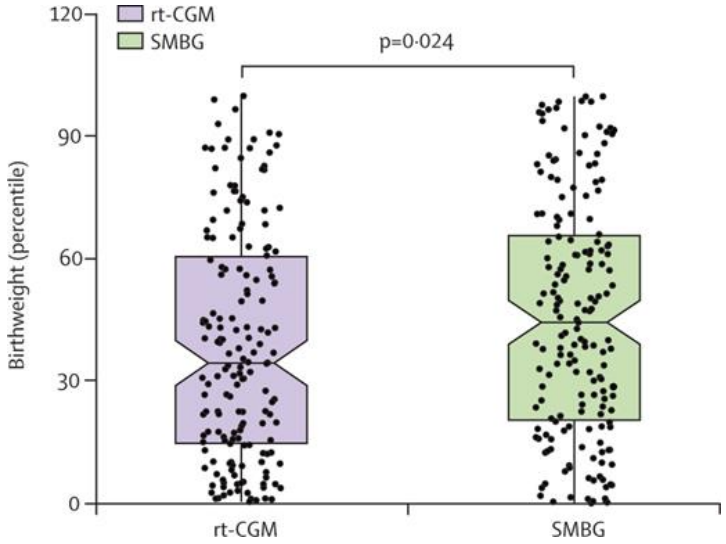
Liang X. The Lancet Regional Health -Western Pacific 2023;39: 100823

Glycaemic control and pregnancy outcomes with rt-CGM in GDM
The GRACE study

- Open-label, multicentre, randomised controlled study
- 375 pregnant women
  - CGM (190 pz)
  - SBGM (185 pz)
- Since August 2020 to May 2024 in Austria, Germany, Switzerland
- GDM diagnosis by OGTT after 24 weeks' gestation



- ✓ rt-CGM use in women with gestational diabetes **reduced LGA births**, without differences in serious adverse events.
- ✓ The higher-than-expected overall prevalence of SGA infants, possibly related to the tight glycaemic control in our cohort, requires further research.

Tina Linder et al. The GRACE study Lancet Diabetes Endocrinol 2025

Glycaemic control and pregnancy outcomes with real-time continuous glucose monitoring in gestational diabetes (GRACE): an open-label, multicentre, multinational, randomised controlled trial

Tina Linder, Iris Dressler-Steinbach, Silke Wegener, Karen Schellong, Saskia Schmidt, Daniel Eppel, Cécile Monod, Florian Heinzl, Katharina Redling, Bettina Winzeler, Beatrice Mosimann, Friederike Weschenfelder, Tanja Groten, Martina Mittlböck, Johan Jendle, Wolfgang Henrich, Micaela Morettini, Latife Bozkurt, Andrea Tura, Christian Göbl, the GRACE study collaborative group

- …reduction in the proportion of LGA neonates might potentially be accompanied by **an increased risk of SGA**.
- Rt-CGM use also led to **increased administration of rapid-acting insulin** and modest enhancement in time in range.
- Consequently, until glycaemic targets for CGM use in gestational diabetes are better defined, **rt-CGM could be considered for selected patients under the supervision of an experienced care team**.

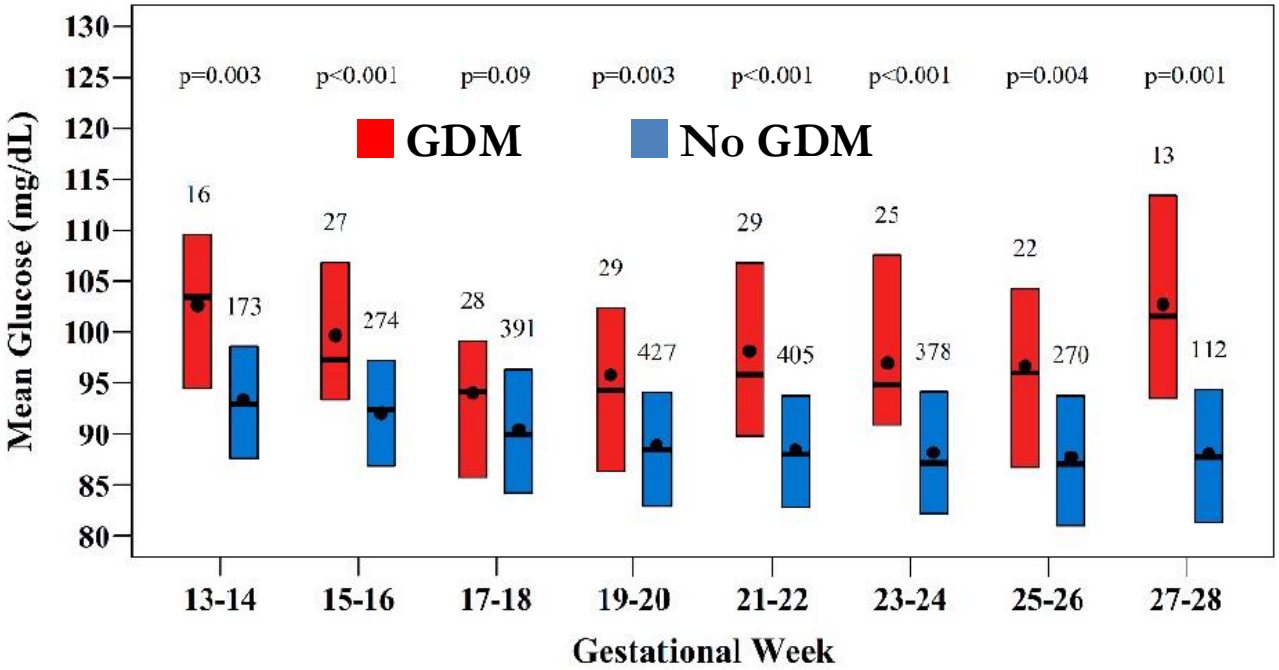
CGM metrics in early pregnancy and risk of GDM
The GLAM study

- Prospective cohort study
- 768 pregnant women <17 gestational week
- Participants wore a CGM as much as tolerated across gestation
- GDM diagnosis by OGTT after 24 weeks' gestation



Durnwald C. Diabetes Care 2024;47:1333–1341

CGM in pregnant women with GDM

Current evidence is ***insufficient*** to recommend CGM routine use for clinical and diagnostic purposes (detecting early gestational diabetes and predicting the development of GDM). However, the use of CGM could be considered for women with **GDM on insulin therapy** to achieve better glycaemic control and improve certain outcomes.

Glycemic targets

- psTIR (63–140 mg/dL): ≥90%.
- psTAR (>140 mg/dL): <5%.
- psTBR (<63 mg/dL): <4%.
- psTBR (<54 mg/dL): <1%.

Importantly, the guideline does not support **simplifying glucose targets to a single 24-h CGM target of < 140 mg/dL**; rather, it recommends maintaining the standard pregnancy glucose targets based on fasting and post-prandial values:

- fasting < 95 mg/dL
- 1-h post-meal < 140 mg/dL
- 2-h post-meal < 120 mg/dL

Conclusions

- SBGM has been the gold standard for blood glucose monitoring in pregnancy for many years and remains an excellent solution for patients managed on diet alone.
- CGM is now a cornerstone of care in type 1 diabetes during pregnancy and has a growing role in type 2 diabetes and gestational diabetes mellitus (GDM).
- Realtime CGM (rtCGM) offers greater benefit than intermittent scanning (isCGM), particularly for insulin-treated patients.
- Pregnancy-specific glycaemic targets remain difficult to achieve, particularly fasting and postprandial goals.
- Moreover, CGM-derived metrics may be useful in early pregnancy for predicting GDM.
- RCTs to further define glycemic targets in pregnancy and refinement of emerging technology to achieve those targets can lead to significant reduction of harm and in the burden of diabetes care
